British Medical Association

annual exhibition 10-14 July 1967

In conjunction with the 135th Annual Meeting at the University of Bristol Union there will be an Exhibition of pharmaceutical products, medical and surgical apparatus, allied services and medical publications.

All members of the medical profession are invited to visit this Exhibition.

Monday, Tuesday, Wednesday and Thursday, 9.0 a.m. till 6.0 p.m.
Friday, 9.0 a.m. till 2.30 p.m.

THE WORLD HEALTH ORGANIZATION

requires from time to time

SPECIALISTS FOR TEACHING ASSIGNMENTS AND ADVISORY WORK IN:

- Preventive and Social Medicine
- Anatomy
- Biochemistry
- Physiology
- Pharmacology
- Microbiology (Parasitology—Bacteriology)
- Immunology
- Pathology
- Internal Medicine
- Psychiatry
- Paediatrics
- Obstetrics
- Epidemiology and Statistics

QUALIFICATIONS: Medical or science degree—minimum of 3 years' experience. For teaching assignments, preferably 3 years' experience in senior academic positions, e.g. Senior Lecturer, Reader, Associate Professor.

LANGUAGES: English or/and French.

Salary: According to grading of post—US $10,800–US $16,000 per annum (net of income tax).

Allowances: (applicable on appointments of at least one year) According to Staff Rules: post adjustment, dependants, assignment, education grant for children, health insurance for staff and dependants.

DUTY STATION: In the following regions: Africa, South East Asia, Western Pacific and Eastern Mediterranean countries.

DURATION OF ASSIGNMENT: Short-term contract of a few months' duration and long-term two years' or more renewable.

All applications should be sent to: **World Health Organization (VN/MS), Avenue Appia, Geneva.** Only candidates under consideration will receive a reply.

For BURNS · WOUNDS · ULCERS

NU-SAN GAUZE is an absorbent, non-greasy dressing, non-adherent to raw wound surfaces, easy to apply and remove.

MY-SAN is a more recent development being closely woven and, because of its special process of manufacture, is even less adherent, making it the dressing of choice for burns, donor sites and septic wounds, as well as for profusely discharging, infected ulcers.

Write for samples and leaflets to **NU-SAN LIMITED**

Obstetrics
in General Practice

Published July 1966

This book is made up of a series of articles printed in the " Current Practice " section of the BRITISH MEDICAL JOURNAL. It is designed to give a lucid and practical account of obstetrics as it is carried out in the patient's home or in a maternity unit, with special emphasis on the role of the general practitioner and his relationship to the consultant obstetrician and the hospital. The principal authors are consultant obstetricians, but to ensure that the general practitioner's own view and special experience should be represented the consultant contributors were asked to prepare their articles in collaboration with general practitioners. The book as a whole is a product of such co-operative effort. It will prove a useful guide to this important branch of medical practice.

Demy Octavo *187 pages*

Opportunities in BRITISH MEDICINE

The Board will comprise:

Dr. R. H. Barrett,
OBE, MRCS, LRCP, DTM & H DPH,
Principal Medical Officer,
Ministry of Health, London.

Professor A. G. W. Whitfield,
PhD, MD, FRCP,
Director of the Board of Graduate Medical Studies,
University of Birmingham.

Dr. A. Talbot Rogers,
CBE, MB, BS, FRCGP
Principal Medical Officer,
Ministry of Health, London.

Dr. Stephen Whittaker,
MA, MD, FRCP,
Consultant Physician and Chairman of the Consultant Services Committee,
Birmingham Regional Hospital Board.

Dr. Christie Gordon,
MB, ChB, MRCP, DPH, Dr.PH (*Johns Hopkins*),
Senior Administrative Medical Officer,
Birmingham Regional Hospital Board.

AN INTERVIEW BOARD sponsored by the Ministry of Health will visit various centres in the

UNITED STATES AND CANADA

during October, 1967, and will be interested to meet British doctors considering a return to medical work in the United Kingdom.

There are career opportunities in most branches of medicine, including administration in the National Health Service.

Payment of fares to the United Kingdom (including family) can be authorised for selected applicants.

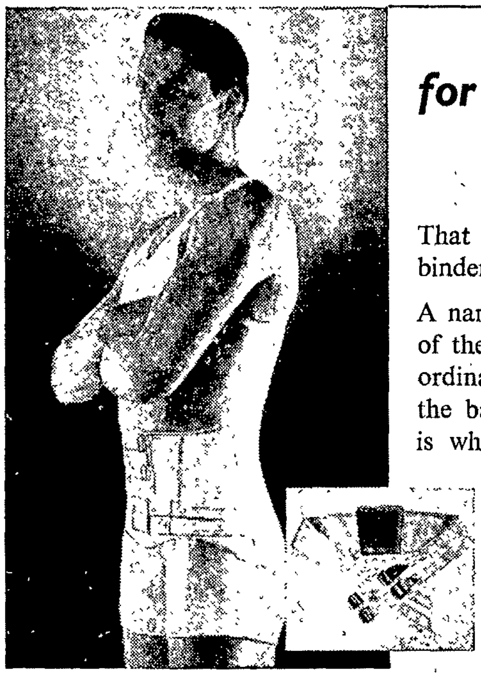
Doctors wishing to avail themselves of these facilities should write to:

Dr. R. H. Barrett, Ministry of Health,
Alexander Fleming House,
LONDON, SE1, ENGLAND,

stating their special interests and work in which they would like to engage in the United Kingdom.

Enquiries will be treated in confidence.

Interviews will be arranged at the centres to be visited by the Board.



for Sacro-iliac strain a narrow belt alone is not enough . . .

That is why Spencer Designers incorporate an easily adjustable pelvic binder (see inset below) inside each Spencer created for Sacro-iliac strain.

A narrow belt alone will not provide adequate continuous immobilization of the sacro-iliac joints, because such a belt will *not* stay in place. With ordinary body movements, any narrow belt alone will ride up and dig in at the back, thus causing faulty posture that increases the disability. That is why every Spencer Sacro-iliac Support is a "belt within a support", designed to the necessary heights and lengths to bridge the lumbar curve and correlate abdominal and back support. Thus improvement in posture—essential to relief in sacro-iliac strain—is attained and maintained.

Every Spencer—for abdomen, back, breasts—is individually designed, cut and made for each patient.

Three Impressive Books from Saunders

Beeson and McDermott: (Cecil-Loeb)

TEXTBOOK OF MEDICINE (New 12th edition)

The publication of this *New* (12*th*) *Edition* precisely 40 years after the first edition indicates how this book through the years has met the exacting demands of the medical profession . . . presenting a contemporary, authoritative and precise picture of virtually every known disease entity. The scope of medicine it embraces today is reflected in the fact that three separate Forewords are utilized in this revision.

Edited by Paul B. Beeson, M.D., *University of Oford,* and Walsh McDermott, M.D., *Cornell University Medical College. With the assistance of* 170 *eminent authorities.*

1,738 pages. Illustrated.

Single Volume **£7 3s. 6d.** Two-Volume Set **£8 11s. 6d.** Also available in a De Luxe Two-Volume Set **£10 10s.**

Sodeman and Sodeman:

PATHOLOGIC PHYSIOLOGY:

Mechanisms of Disease

(New 4th edition)

This book is designed to bridge the gap between the standard texts on physiology and textbooks of medicine. It presents a modern clinical picture of disease as resulting from physiological disturbance or dysfunction. Its twenty-eight distinguished contributors represent a vast storehouse of experienced, up-to-date, medical knowledge.

Edited by William A. Sodeman, M.D., Sc.D., F.A.C.P., *Jefferson Medical College;* and William A. Sodeman, Jr., M.D., *University of Michigan Medical School. With* 28 *contributors.*

1,051 pages. Illustrated. **£6 13s. 0d.**

Robbins: PATHOLOGY

(New 4th edition)

The new edition of *Pathology* will give you the clearest possible portrait of the dynamics of diseases as they are understood today. Dr. Robbins has almost completely rewritten his popular text to give you deeper insight into diseases from their origins to their most advanced stages.

By Stanley L. Robbins, M.D., *Professor and Chairman, Department of Pathology, Boston University School of Medicine, Boston, Mass.*

1,434 pages. Illustrated.

Single Volume **£7 3s. 6d.**
Two-volume Set **£8 15s. 0d.**

CHILD CARE

Published 1 January, 1967

This book is the second to be published from a series of articles that have appeared in the "Current Practice" section of the *British Medical Journal*. It gives practical up-to-date advice on problems faced by general practitioners. The articles that make up the book cover the period from infancy to adolescence, and in their scope cover child-care in the broadest sense, with sections on normal development, adoption, puberty, and behaviour disorders as well as the diagnosis and management of childhood diseases. The authors are consultant paediatricians or leading authorities in their fields, but the emphasis throughout has been on a practical approach. It is hoped that the book will be a useful guide for all family doctors.

Treatment of common skin diseases

Published July 1967

Patients with skin diseases take up a large part of the time of busy general practitioners and the number of preparations available for the treatment of these disorders is rising each year. Treatment of Common Skin Diseases is a collection of articles, specially written for the *British Medical Journal,* designed to give practical advice on the management of these diseases and the selection of remedies. The articles are easy to read and give full details of dosage and administration of drugs, advice on diet, and answers to the questions asked by patients and their relatives.

For BURNS · WOUNDS · ULCERS

MY-SAN NU-SAN

NU-SAN GAUZE is an absorbent, non-greasy dressing, non-adherent to raw wound surfaces, easy to apply and remove.

MY-SAN is a more recent development being closely woven and, because of its special process of manufacture, is even less adherent, making it the dressing of choice for burns, donor sites and septic wounds, as well as for profusely discharging, infected ulcers.

Obstetrics in General Practice

Published July 1966

This book is made up of a series of articles printed in the "Current Practice" section of the BRITISH MEDICAL JOURNAL. It is designed to give a lucid and practical account of obstetrics as it is carried out in the patient's home or in a maternity unit, with special emphasis on the role of the general practitioner and his relationship to the consultant obstetrician and the hospital. The principal authors are consultant obstetricians, but to ensure that the general practitioner's own view and special experience should be represented the consultant contributors were asked to prepare their articles in collaboration with general practitioners. The book as a whole is a product of such co-operative effort. It forms a useful guide to this important branch of medical practice.

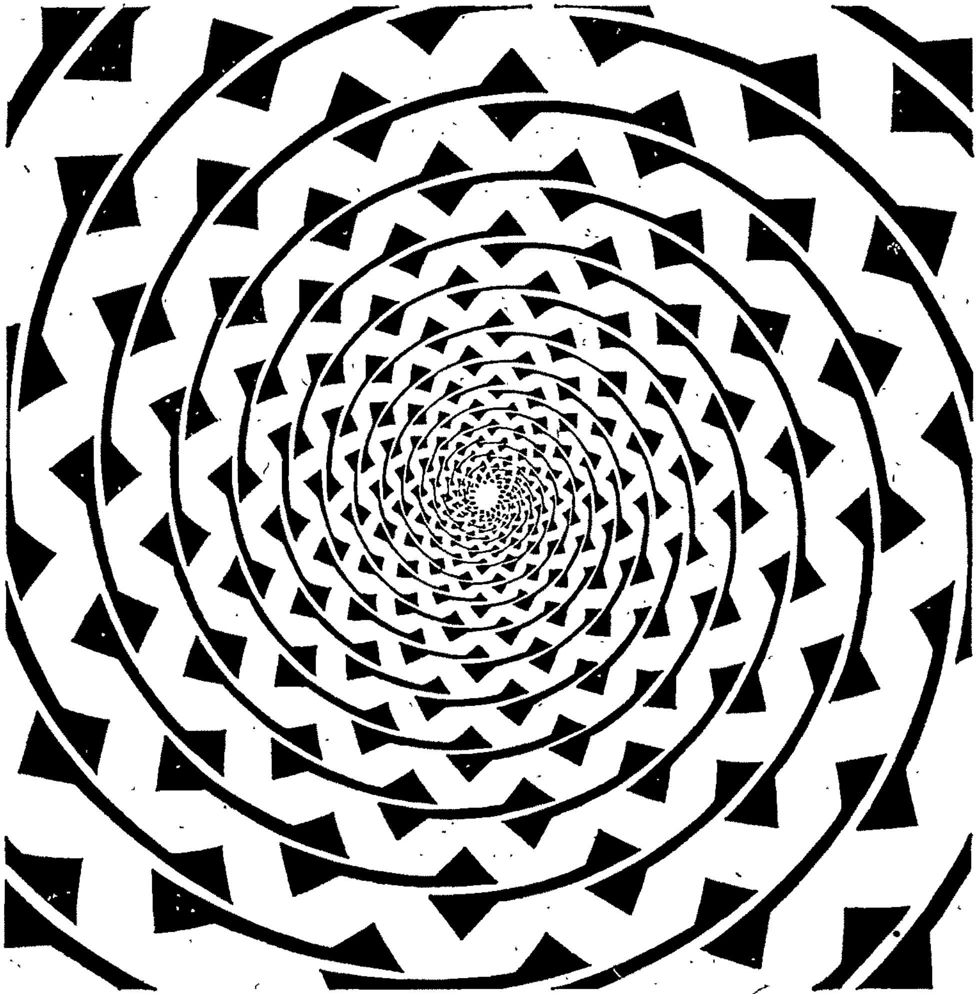
A spiral or concentric circles?



clinical studies show pain relief is no illusion with

PONSTAN

Ponstan* (mefenamic acid, Parke-Davis) has superior analgesic, anti-inflammatory and antipyretic properties . . . is effective in a wide variety of conditions including chronic rheumatic disorders, acute pain of most aetiologies and pyrexial conditions . . . is well tolerated with an impressive absence of serious toxic effects . . . is less liable to cause gastro-intestinal haemorrhage than acetylsalicylic acid. Ponstan is available in Kapseals* of 250 mg. in containers of 12, 100 and 500, and as a suspension containing 50 mg. mefenamic acid per 5 ml. in bottles of 60 ml.

Obstetrics in General Practice

Published July 1966

This book is made up of a series of articles printed in the " Current Practice " section of the BRITISH MEDICAL JOURNAL. It is designed to give a lucid and practical account of obstetrics as it is carried out in the patient's home or in a maternity unit, with special emphasis on the role of the general practitioner and his relationship to the consultant obstetrician and the hospital. The principal authors are consultant obstetricians, but to ensure that the general practitioner's own view and special experience should be represented the consultant contributors were asked to prepare their articles in collaboration with general practitioners. The book as a whole is a product of such co-operative effort. It will prove a useful guide to this important branch of medical practice.

The problem of the dirty mouth

Even in 1967 the dangers, and the unpleasantness, of the dirty mouth are still present in the post-operative period, as well as in many fevers; the geriatric patient being especially prone to them. Careful attention to oral hygiene will usually, of course, keep the patient comfortable and prevent complications. Such attention, however, is very time-consuming to the nurse; and it is not often realised that for most patients it can be replaced or supplemented by the use of chewing gum.

The regular use of chewing gum, by stimulating salivary flow, keeps the mouth clean in the most natural way possible. The patient is in a sense providing his own nursing care with the minimum of energy expenditure by himself.

Child patients, of course, need no encouragement to chew gum. The older patient may need encouraging—but not once he has appreciated the very obvious cleansing and refreshing effect that chewing gum has upon the mouth. Chewing gum is also of value to patients who are forbidden to smoke.

Indispensables

Certain things are *basic* . . . The books, for instance. You may not take them down every day, but you *know* them. Sound, fundamental.

You know Aspellin, too. A really effective, economical treatment for rheumatic conditions and muscular trauma—a spirit-based liniment containing Acid Acetylsalicylic to relieve symptomatic pain *rapidly*, and Methyl Salicylate, with Menthol and Camphor, to reduce inflammation and muscle tension.

Rheumatism sufferers can only obtain Aspellin if you prescribe it. Aspellin is *only* obtainable on prescription. Cost: 10½d. per oz.

ASPELLIN—*indicated in the treatment of acute rheumatic conditions, sciatica, lumbago, fibrositis, muscular trauma.*

Tissue and Organ Transplantation

The Proceedings of a Symposium organised by the College of Pathologists

Genetic background and transplantation antigens • Action of lymphocytes in transplantation • The role of the macrophage in transplantation immunity • Humoral and cell-mediated effector mechanisms in tissue transplantation • Immunological tolerance • The response of draining lymph nodes to immunological stimulation in intact and thymectomized animals • Immunological properties of antilymphocytic serum • Immunosuppressive agents and allogeneic transplantation • Immunosuppressive action of ribonucleases • The relevance of leucocyte antigens for allogeneic renal transplantation • The transplantation of cartilage • Rejection in treated renal allografts • Grafts of haemopoietic tissue: the nature of haemopoietic stem cells • Bone transplantation.

PRICE 30s. (U.S.A. $4.50) including postage

The Thyroid Gland

The Proceedings of a Symposium organised by the Association of Clinical Pathologists

The structure of the thyroid gland • The biosynthesis of thyroid hormones • The action of thyroid hormones • The control of thyroid secretion • The radioimmunoassay of thyroid-stimulating hormone in human blood • Carriage of circulating thyroid hormones and the estimation of total plasma hormone levels • The estimation of thyroid hormone binding by plasma proteins and of unbound levels of thyroxinein plasma • The value of inorganic iodine studies in the clinical assessment of thyroid disease • Stimulation and suppression tests of thyroid function • Tests based on the peripheral action of thyroid hormone • Aetiology of hyperthyroidism • The diagnosis of hyperthyroidism • Hypothyroidism • Hypothyroidism due to congenital dyshormonogenesis • Thyroid autoimmune disease • Extrathyroidal thyroglobulin • Medullary carcinoma of the thyroid • Thyrocalcitonin.

PRICE 30s. (U.S.A. $4.50) including postage

Treatment of common skin diseases

Published July 1967

Patients with skin diseases take up a large part of the time of busy general practitioners and the number of preparations available for the treatment of these disorders is rising each year. Treatment of Common Skin Diseases is a collection of articles, specially written for the *British Medical Journal,* designed to give practical advice on the management of these diseases and the selection of remedies. The articles are easy to read and give full details of dosage and administration of drugs, advice on diet, and answers to the questions asked by patients and their relatives.

Three Unique Anticholinergics

with exceptional therapeutic characteristics

PIPTAL

(Pipenzolate methobromide)

For Peptic Ulcer

Piptal decreases acid secretion, suppresses abnormal gastric motility and relieves the pain of peptic ulcer.
It is unusually well-tolerated, even when administered over long periods.

DACTIL

(Piperidolate hydrochloride)

For Gastro-duodenal Spasm

Dactil selectively relieves pain due to upper gastro-intestinal spasm usually within ten minutes. Indications include abdominal cramps as in gastro-duodenal spasm, as well as biliary spasm, hiatus hernia, cardiospasm, pylorospasm, post-gastrectomy syndrome and regional ileitis.

CANTIL

(Mepenzolate bromide)

For the Colon

Cantil effectively relieves pain due to colonic spasm in irritable colon, spastic colitis and diverticulitis. It counteracts colonic hypermotility in acute and chronic non-specific diarrhoeas, mucous colitis and ulcerative colitis.

SIDE EFFECTS have only rarely been observed. The selective actions of all three products —*fully supported by extensive clinical trials*—have been found to provide a high degree of therapeutic efficacy with almost complete freedom from the side effects commonly attributable to anticholinergic drugs.

CONTRA-INDICATIONS—Piptal, Dactil and Cantil are contra-indicated in glaucoma and should be used with caution in prostatic hypertrophy.

Special Allowances in General Practice

1. A £400 a year special allowance

is made to principals providing full general medical services in areas which, for three years or more, have been continuously designated by the Medical Practices Committee as needing more doctors. These areas are:

Bedfordshire: Luton.
Buckinghamshire: Cippenham; Slough; Taplow and Burnham
Cambridgeshire: Wisbech.
Cheshire: Crewe and Haslington.
Cumberland: Carlisle.
Derbyshire: Chesterfield; Heanor; Swadlincote.
Durham: Billingham; Darlington; Easington, Houghton-le-Spring; Seaham; Sedgefield; Stanley; Stockton-on-Tees with Norton-on-Tees; Sunderland; Washington; West Hartlepool.
Essex: Basildon; Benfleet; Southend; Wickford.
Hampshire: Bishopstoke; Chandler's Ford; Eastleigh; Fair Oak.
Hertfordshire: Hertford; Potters Bar; Stevenage,
Kent: Dartford; Gravesend; Northfleet; Rochester.
Lancashire: Accrington; Ashton-under-Lyne; Blackburn; Bootle; Chorley; Denton; Droylesden and Audenshaw; Failsworth; Great Harwood; Haydock; Irlam; Leigh; Manchester; Middleton; Oldham; Preston; Rochdale; St. Helens; Widnes; Worsley.
Leicestershire: Leicester.
Lincolnshire (Holland): Spalding.
Lincolnshire (Kesteven): Grantham.
Lincolnshire (Lindsey): Cleethorpes; Scunthorpe.
Greater London: Canning Town; Custom House; Dagenham; Silvertown; East Ham; Feltham; Hayes and Harlington; Hornchurch.
Northamptonshire: Kettering.
Nottinghamshire: Hucknall; Nottingham; Sutton-in-Ashfield; Worksop.
Salop: Wellington.
Staffordshire: Brierley Hill; Cannock; Coseley; Darlaston; Newcastle-under-Lyme; Rowley Regis; Rugely; Sedgley; Stoke-on-Trent; Stone; Tamworth; Tipton; Walsall; Wednesbury; West Bromwich; Wolverhampton.
Warwickshire: Birmingham; Coventry; Kingsbury/Polesworth; Nuneaton; Rugby.
Worcestershire: Dudley.
Yorkshire (East Riding): Kingston upon Hull.
Yorkshire (North Riding): Middlesbrough.
Yorkshire (West Riding): Barnsley; Bentley with Arksey; Bradford; Castleford Borough; Dewsbury; Hatfield and Stainforth; Hemsworth; Leeds; Maltby; Morley; Rotherham; Royston; Sheffield; Stockbridge; Worsborough.

2. An initial practice allowance

is also payable to a doctor who is
(a) setting up a new single-handed practice,
(b) filling a vacancy in a small single-handed practice,
(c) joining, as an additional partner, an existing practice which has a very large list.

This applies in *all areas* classified by the Medical Practices Committee as 'designated' and not only in those quoted above.

Full details of the circumstances in which these allowances are payable, the extent of the income guaranteed by them, and the latest list of designated areas may be obtained from the Ministry of Health. If you are interested, please write for these details to:

Psychological Factors in Ulcerative Colitis

For many years it has been widely accepted that psychological factors are prominent in ulcerative colitis. Some physicians indeed go so far as to regard ulcerative colitis as a psychosomatic disease in the strict sense of this term—namely, as an illness in which the organic lesions are the consequence of emotional disturbances.

An extensive literature exists on the psychological aspects of the disease. Perhaps the outstanding pioneer was C. D. Murray,[1] who in 1930 investigated twelve patients from the psychological viewpoint. He found "a well-marked time-relationship between the outbreak of an emotional disturbance and the onset of the symptoms." Mental conflicts concerned with marriage were the most common source of anxiety, and he judged that the patients faced their problems in an inadequate and infantile manner. E. Wittkower[2] made personality studies of 40 unselected patients with ulcerative colitis and found that psychological abnormalities and disorders far beyond the range of individual differences in the normal population existed before the onset of the colitis in the majority. Furthermore, in 28 of the 40 patients "a clear-cut emotional trauma, serious enough to be regarded as a precipitating agent, immediately preceded the onset of the colitis."

The psychosomatic hypothesis was fully reviewed by G. L. Engel[3-5] in articles dealing with 39 of his own patients and the published reports on 700 others. He found that four factors emerged "with impressive consistency": defects in personality long preceding the colitis; dependent and restricted relationship with other people; psychopathology in the mothers; and failure to achieve full heterosexual development.

Some physicians[6 7] have been so impressed by the importance of psychological factors in ulcerative colitis that they have regarded psychotherapy as the mainstay of treatment. Some objective evidence that psychotherapy can be beneficial comes from W. J. Grace, R. H. Pinsky, and H. G. Wolff.[8] They compared two matched groups of 34 patients in the first of which the management was by one physician (W. J. G.) with the emphasis on superficial psychotherapy aimed at relieving stress, whereas the second group was managed by various physicians who relied on diet, medication, and antibiotics. The psychotherapeutic group fared better than the control group, but even so the results do not appear impressive.

While many of the psychiatric studies of ulcerative colitis have been on individuals or on small groups of patients and are thus necessarily subjective and anecdotal, some workers have attempted to provide objective evidence. For example, L. Krasner[9] made use of a battery of intelligence and personality tests, including the Guilford–Martin factor inventory, to compare two groups of patients suffering from "psychosomatic diseases" (duodenal ulcer and ulcerative colitis) with a control group

© *British Medical Journal*, 1967. All reproduction rights reserved.

of patients who had never suffered from any of the diseases often considered to be psychosomatic. The group with ulcerative colitis did best in the intelligence test, but their results did not depart significantly from the normal distribution. Personality differences between the ulcerative colitis group and the control group were revealed by significant differences in scores on the Guilford–Martin factor inventory, the results tending to confirm previous descriptions of the ulcerative patients as being passive, insecure, shy, sensitive, and moody.

The article by Drs. F. Feldman, D. Cantor, S. Soll, and W. Bachrach which appears at page 14 of the *B.M.J.* this week must be one of the few psychiatric studies to discount the importance of psychological factors in the aetiology of ulcerative colitis. Its sharp disagreement with most of the conclusions reached by earlier authors is bound to excite controversy, which can hardly fail to be beneficial. The study consisted of a psychological evaluation of 34 patients with ulcerative colitis and a comparison with the general population and also with 74 patients admitted for other gastroenterological conditions. In essence, on the basis of scoring 65 variables, the subjects were placed in five categories of normality or abnormality. The great majority of the patients were classified as "normal" as regards personality and psychiatric illness. In only a small number was there an emotional precipitant closely preceding the first attack of ulcerative colitis. Seven of the patients had undergone extensive psychiatric treatment after the onset of ulcerative colitis. In three of these psychotherapy had helped the patient to adjust to his illness, but in none did it appear to have had any appreciable effect on the course of the disease.

Some support for the iconoclastic view of Feldman and his colleagues comes from the epidemiological study by E. D. Acheson and M. D. Nefzger[10] of ulcerative colitis in the United States Army. They were able to match each case with a control subject of the same rank, age, and sex, and it is interesting that they found no appreciable difference in intelligence, educational attainments, income before enlistment, or military conduct. M. Monk[11] made a study in Baltimore designed to uncover differences in social environment between patients with ulcerative colitis and the population from which they came. She found no differences in educational attainments, amount of life lived with parents or alone, degree of social contact with others before the onset of the illness, or the number of bereavements or marital disagreements in the month preceding the symptoms. However, she did show that the ulcerative colitis group were more likely to have fathers who had died during the patient's childhood. Does this positive finding support the view of J. W. Paulley[12] that "the disease is associated with a well-defined personality not uncommonly related to the unfortunate effect of overpossessive mothers"?

Hospital Junior Staff

The wisdom of giving autonomous powers to sectional interests within the B.M.A., which exists to represent the medical profession as a whole, has often been questioned. The exercise of autonomy has on occasions seriously strained intraprofessional relations. Yet to those who possess it the advantages of autonomy have always seemed to outweigh its disadvantages, and under the new B.M.A. constitution, which the Annual Representative Meeting at Bristol next week is likely to approve, the autonomous powers of the committees representing the major branches of medical practice will be strengthened rather than weakened. It is therefore not surprising, nor unreasonable, that there should be renewed demands from hospital junior medical staff for the same rights of self-government as their seniors in established practice have.

However, the wish for autonomy is by no means universal among hospital junior doctors. Some think they would fare no better with it and perhaps less well. The Hospital Junior Staffs Group Council, which represents hospital junior doctors in the B.M.A., is against breaking away from the Central Consultants and Specialists Committee (or, as it will be named, the Committee for Hospital Medical Services), on which junior doctors will in future have twelve representatives instead of four. It is to be hoped, therefore, that the Junior Hospital Doctors' Association, the prime mover in the demand for autonomy, will not press the matter too hard. It would be a pity if this association went so far as to demand the right to negotiate separately on behalf of its members, as its chairman has stated[1] it will in the event of failing to get antonomous powers for hospital junior staff within the B.M.A. That would create an unfortunate division.

It is doubtful whether any organization could completely overcome the problems in representing the interests of a group of doctors so disparate as hospital junior staff. The personal and professional concerns of a middle-aged senior registrar experienced in a specialty and those of a newly fledged, provisionally registered houseman uncommitted for the future are far apart. But both rank as hospital junior staff—as do a British-born registrar intent on becoming a consultant and his colleague from the Commonwealth wanting postgraduate experience. It is difficult to make a convincing case for autonomy for what may be called the "junior" hospital junior staff, whose future may lie in any branch of medicine. Their membership of the hospital population is surely too transient to make it worth while for them to try to create the elaborate and expensive machinery needed for self-government. The more senior among the junior staff are in the main committed to a hospital career, and their interests are as much in what their terms of service are likely to be on promotion as in what they currently are. Their polarity must be towards the top of the ladder.

Last week the Council of the B.M.A. approved the Hospital Junior Staffs Group Council's proposals for reorganizing the constitution of the Group Council itself and of its constituent regional groups. The number of representatives from the regions on the Group Council are to be increased from 42 to 50. The total membership of the Group Council will be 60 instead of 48, and of the 60 only two will be appointed by the Central Consultants and Specialists Committee. Participation in the affairs of the Group is to be open to all hospital junior staff, whether members of the B.M.A. or not.

---

[1] Briggs, J. H., *World Medicine*, 1967, **2**, 15.
[2] *Brit. med. J. Suppl.*, 1967, **2**, 45.

The local organization is to be based on hospital meetings, and these will elect the regional committees. The larger regions will have bigger regional committees who, in turn, will appoint a larger number of representatives on the Group Council.

These new arrangements give ample scope for democracy to work. The Hospital Junior Staffs Group Council should be able in future fairly to claim that it represents all hospital junior doctors. Its executive committee is to appoint 12 members of the Central Committee for Hospital Medical Services, and this committee is in future to be responsible, through a Negotiating Subcommittee, for remuneration and all terms of service for all hospital doctors.[2] Three of the Central Committee's nine representatives on the Negotiating Subcommittee are to be hospital junior staff members.

Hospital junior doctors will not only have more opportunity to make their voice heard centrally and round the negotiating table but also more power, and therefore more responsibility, in shaping the future of the hospital services as a whole. It would surely be better for them first to try out their new power alongside their senior colleagues rather than independently of them and, sometimes needlessly, in opposition. The medical profession has enough to contend with without also having contention in its own ranks.

Segregation of Tuberculous Patients

Removal of patients with infectious pulmonary tuberculosis from their homes in an attempt to protect the family has been generally accepted as a sound preventive measure. This policy now needs reappraisal.

How effective and necessary is segregation of patients receiving modern chemotherapy, which rapidly reduces infectivity ? This question has been investigated in Madras by the Tuberculosis Chemotherapy Centre. It has reported a five-year controlled study of the attack rate of tuberculosis among close-family contacts of patients with newly diagnosed infectious pulmonary tuberculosis.[1] The contacts lived in poor, overcrowded conditions and all had been living, feeding, and cooking with the patients for at least three months before the diagnosis was made. None of the contacts were given B.C.G. vaccination or chemoprophylaxis. Attack rates were studied in family contacts whose only infectious member was initially the index case. A comparison was made between 272 "sanatorium" family contacts, whose index case was isolated in a sanatorium for one year, and 256 "home" contacts, who remained exposed to the index case during treatment at home. The study covered five years. Both home and sanatorium patients received isoniazid and sodium P.A.S. (sodium para-aminosalicylic acid) for one year. By the end of it in 86% of the home and 92% of the sanatorium patients the disease was bacteriologically quiescent.

During the five years' follow-up tuberculosis developed in 9% of the home and 14% of the sanatorium contacts, including 5% and 7% respectively in the first year. About one-third of the contacts were initially tuberculin-negative. Among these the attack rate of tuberculosis over the five years was 10% in the home series and 11% in the sanatorium series, including 8.1% and 8.0% respectively in the first year. The corresponding figures for the initially tuberculin-positive contacts were 9% and 16% over the five years and 3% and 7% in the first year. Thus the risk of developing tuberculosis was no greater for the home contacts than it was for the sanatorium contacts either over the whole five-year period or even in the first year.

The sanatorium contacts were exposed to the risk of infection from two sources—firstly, from the patient before the diagnosis of tuberculosis had been made, and, secondly, from other sources in the urban community in which the family lived. The home contacts were exposed to both these risks and in addition to that of continued contact with the patient during home treatment. Exposure to the patient during treatment at home was not an important risk, since the attack rate was similar in the tuberculin-negative contacts in the two groups, while in the tuberculin-positive contacts it was actually higher in the sanatorium group—apparently by chance. The main risk to the contacts seemed to be from exposure to the patient before diagnosis. The continued contact with the patient at home during treatment was little extra hazard.

This demonstration that well-organized domiciliary treatment is practicable, effective, and safe for family contacts is of great importance in developing countries with shortage of sanatorium beds.[2] [3] In Britain facilities for domiciliary treatment are good, yet many physicians admit almost all the sputum-positive patients to hospital for several months. This policy can hardly be justified on the grounds of risk to family contacts, for it proved to be unnecessary in the overcrowded conditions of Madras. The risk is likely to be even less in Britain, where patients can often be isolated in their own home. Moreover, B.C.G. vaccination and chemoprophylaxis are freely available for suitable contacts and are known to be effective in preventing tuberculosis.[4] [5] It is thus reasonable to conclude that, although there may be several good reasons for treating pulmonary tuberculosis in hospital, admission cannot be regarded as essential to prevent infection of the family contacts of co-operative patients from good homes, who can be given well-supervised domiciliary chemotherapy.

Oedema in Pregnancy

Many clinical interpretations have been put on oedema in pregnancy. The relationship of this physical sign to gain in weight and to pre-eclamptic toxaemia is not fully understood Nor is it clear to what extent oedema means an increase i the total amount of water in the body or a change i the distribution of water between plasma, tissue fluid, an intracellular fluid.

Since these matters have probably been oversimplified, recent study by A. M. Thomson, F. E. Hytten, and W. Billewicz[1] is of special interest. They examined the recor of 24,079 women living in Aberdeen who had given birth single, legitimate babies. From the records they were al to recognize women who had no oedema, those with oede of the legs only, and those with generalized oedema—that elsewhere than in the legs and ankles. They also classif the women as normotensive or hypertensive (diastolic press (of 90 mm. Hg or more), and as being pre-eclamptic when there was proteinuria in addition to hypertension.

In the normotensive women oedema, mainly of the legs, increased with age, being present in 14% of those under 20 years of age and in 29% of those over 30. Preliminary evidence suggested that women who had been oedematous in one pregnancy were twice as likely to develop oedema in a subsequent pregnancy as those who did not have this sign. Women too heavy for their height at 20 weeks of pregnancy were more likely to have oedema, usually of the generalized type, than those of average weight or less. If overweight women gained weight at the rate of 1.2 lb. (545 g.) or more per week from 30 to 36 weeks of pregnancy, there was a 42% chance that they would have generalized oedema and a 24% chance that they would develop oedema of the legs. When the rate of weight gain was less, so was the chance of developing oedema. It should be emphasized that these were the changes found in normotensive women.

When the blood pressure rose above 90 mm. Hg the incidence of oedema, particularly of the generalized form, rose too, and such generalized oedema was even more likely when there was proteinuria as well. Oedema of some kind was present in 35% of normotensive women, 65% of hypertensive, and 85% of those with pre-eclampsia as defined. It is perhaps worth noting the considerable numbers of women who did not have clinically recognizable oedema even when they had hypertension with or without proteinuria.

In general, women with oedema tended to have larger babies than those who did not have oedema, though the difference was only 0.17 lb. (77 g.). The prematurity rate was, on the average, less when there was oedema, especially of the legs, while the perinatal mortality rate was the same whether there was oedema or not. The conclusion the authors reach is that "Oedema, in the absence of other evidence of pre-eclampsia, is associated with a slight advantage in terms of birthweight and incidence of low birthweight, and is not associated with any disadvantage in terms of perinatal mortality. To that extent, it is possible to affirm that oedema in pregnancy is not necessarily harmful and unphysiological." This careful investigation therefore begins to put oedema in perspective.

Hytten, Thomson, and N. Taggart[2] investigated total body water in pregnancy. In 93 patients at least three readings of total body water were made in pregnancy and one 6 to 8 weeks after delivery, all the patients being clinically normal. The mean body water gained in pregnancy amounted to 8.5 kg. Between 10 and 38 weeks of pregnancy the gain in body water was 6.84 kg. in women with no oedema, 7.19 kg. in those with oedema of the legs, and 9.80 kg. in those with generalized oedema. It seems probable that those without oedema held between 1 and 2 litres of water in the extracellular spaces. The women with generalized oedema would appear to hold a further 3 litres somewhere which cannot be accounted for in the products of conception, the uterus, or elsewhere. Such women can be essentially normal, eing healthy themselves and having normal babies. If the weight of the total body water gained is deducted from the otal gain in weight, the "dry weight" gained can be stimated. When this is done it is found that overweight atients put on less "dry weight" than do those who are of average weight for height or underweight. This "dry weight" is probably mainly fat when it cannot be accounted for in other known factors of the total weight gain. The conclusion seems to be that those women who have large fat stores already do not store much extra in pregnancy, while those with small fat stores lay down some more fat.

Hytten and Thomson[3] measured total body water in six patients who developed pre-eclampsia as shown by a rise in blood pressure, proteinuria, and some oedema. The amount gained was within the limits found in normal women without pre-eclampsia, though the rate of gain of water in the last ten weeks of pregnancy was faster than in normal women with generalized oedema.

It is still not easy to assess the significance of oedema in the individual pregnant patient, but this work shows that age, oedema in a previous pregnancy, site of oedema, weight-for-height ratio, blood pressure, proteinuria, and rate of weight gain may all have to be taken into account. Oedema of itself would not seem to be invariably a bad prognostic sign and indeed might signify a slightly better prognosis for the baby when all other factors are considered. This work helps to clarify the relationship between oedema and increase in total body water in pregnancy, but the difference between normal and pre-eclamptic pregnancy in terms of water metabolism is still conjectural.

Investigating Hypertension

In general the significance of a patient's renal lesion to his hypertension is difficult to decide. For instance, renal-artery stenosis may occur with[1] or without[2] hypertension. Thus there is still no single reliable investigation for selecting those hypertensive patients with unilateral renal disease who may be expected to benefit from surgery.

The help of various complex inpatient investigations is sought before resorting to surgical operation. They include aortography, possibly with renal-function studies of each kidney, assay of pressor substances in systemic or renal circulation, angiotensin-infusion tests, studies of renal blood flow, and bilateral renal biopsy. These are formidable tests to put any patient through, and it is not easy to find agreement on which patients should be subjected to them. H. W. Smith[3] estimated the incidence of curable renal hypertension to be at most 2% of all hypertensive patients. This fairly gloomy picture is confirmed by M. J. Chamberlain and J. A. Gleeson,[4] who found that in a series of patients subjected to aortography the number permanently benefited by surgery was unduly small in relation to the morbidity of the investigation and later operation. But a higher proportion of cases of correctable renal hypertension has been reported by M. E. DeBakey and colleagues[5] and E. F. Poutasse.[6] A compromise figure, 5–10%, of renovascular hypertension has been proposed by M. H. Maxwell and G. B. Prozan,[7] who thought that the great majority of such patients could benefit from surgery. In Britain renal-artery stenosis has been reported in 10% of hypertensive patients at aortography,[8] and the surgical treatment of carefully selected patients has certainly been rewarding.[9 10]

Viewed against this background any advance in the accuracy of outpatient screening tests to select patients for more complex inpatient studies would be welcome. If the small number of potentially curable patients could be detected with some certainty at this stage many others might be spared fruitless further investigation. The standard intravenous pyelogram (I.V.P.) is not adequate to this end, failing to select about half of those with renovascular hypertension.[5 11] It gives excellent information about important correctable lesions like unilateral hydronephrosis, pyelonephritis, or tuberculosis, but these play only a small part in renal hypertension. In cases of unilateral renal ischaemia major structural changes in kidney or ureter may be evident. Attempts to improve the diagnostic value of the I.V.P. have been based on studies of asymmetric patterns in the excretion of contrast medium deriving from the selective sodium and water reabsorption in the ischaemic kidney.[12]

Films taken at minute intervals after the injection of contrast medium show up any delay in the appearance of contrast, and this technique has been of help in some hands.[13] However, when differences between the two sides are small, perhaps a minute or less, interpretation can be difficult.[14] Increased density of contrast medium due to marked reabsorption of water in the affected kidney can also cause confusion. To accentuate the asymmetry of contrast density K. Amplatz[15] proposed establishing an osmotic diuresis in the course of the I.V.P. by infusion of urea, thus allowing comparison between the rapid wash-out of contrast from the normal kidney with contrast retention in the ischaemic, oliguric kidney. The early reports of this technique of "radiological divided renal-function studies" suggested a much-improved detection rate of renovascular hypertension, with no false-negative results in the sense of failures to select patients improved by surgery, though "pseudo-positive" results to the test were reported.[16 17] M. H. Schreiber and colleagues[18] have recently laid down a range for the normal and shown that the test does not contribute to the diagnosis of bilateral renovascular disease. The whole place of "wash-out" pyelograms in this field has now been questioned by D. M. Witten and his colleagues,[19] who used mannitol infusion during the I.V.P. in preference to urea, to avoid the latter's potential hazards.

If the success rate of the intravenous pyelogram in the diagnosis of renovascular hypertension can be increased only from 50% to between 60% and 70% by these various refinements it is reasonable to look in other directions for a complementary outpatient screening test of individual renal function. After an uncertain start the hippuran radioisotope renogram has for some time been used with success.[20-22] The careful work of R. G. Luke and his colleagues[23] has now confirmed it as a simple, safe, and rapid investigation in the search for renovascular hypertension. Performed with care and used in conjunction with an initial I.V.P., the incidence of false-negative and false-positive assessments can be kept below 5%.[24] This is a fairly good rate of detection, and one that materially helps to prevent fruitless further investigation.

On present-day evidence the best way of selecting those hypertensive patients who may benefit from further inpatient investigation into a renal cause of their disease is to perform an intravenous pyelogram, supplemented by radiographs during the first five minutes of the examination, and to follow this with a radioisotope renogram.

Mediastinal Emphysema

Mediastinal emphysema has the distinction of being one of the very few conditions which enable the heart beats to be heard from the foot of the bed. With the stethoscope the "crunching" sound described by L. Hamman[1] is usually heard best down the left border of the heart; it varies in intensity and may be absent. If the sign is associated with subcutaneous emphysema of the neck or chest the diagnosis of mediastinal emphysema is virtually certain. The radiological appearances are characteristic, showing a small air space running parallel to the left, and sometimes the right, border of the heart. There may be an associated pneumothorax.

Air may enter the mediastinum by any of several routes. The commonest, as in so-called benign mediastinal emphysema, seems to be through the pulmonary alveoli, when a small rupture causes a pressure gradient between the alveoli and adjacent connective tissue.[2] The mechanism of such a gradient is obscure, but it seems at times to be precipitated by pulmonary emphysema, asthma, pneumonia, or childbirth. Once the air has entered the tissue it takes the line of least resistance and passes along the perivascular sheaths to the mediastinum and thence to the subcutaneous tissue. Ordinarily it does not extend far beyond the neck and in the benign form subsides within a few days. But occasionally the air spreads beyond the neck to the hand, arms, trunk, and even the legs, in which case there is a danger of suffocation. The other possible complication is the so-called "malignant" form of mediastinal emphysema, in which the pressure of air in the mediastinum becomes excessive and embarrasses the action of the heart. This can be fatal, especially if tension pneumothorax coexists.

Other modes of entry of air into the mediastinum include rupture of the trachea, bronchus, or oesophagus from any cause and penetrating wounds of the lung and mediastinal pleura. These are clearly formidable conditions and must always be considered in patients who develop mediastinal emphysema.

There are thus two different clinical problems. In the commoner, benign, form a patient may present with no more than a vague precordial ache,[3] possibly with Hamman's sign and some subcutaneous emphysema of the neck. A careful watch needs to be kept in case complications develop, but usually the prognosis is excellent. If the emphysema spreads or the patient becomes breathless or shows signs of collapse, immediate removal to hospital, preferably to a thoracic surgical unit, is essential. A radiograph of the chest will confirm the mediastinal emphysema; it will also show a pneumothorax and the extent of any preceding trauma. If oesophageal rupture is suspected, surgical treatment is imperative as soon as possible. The diagnosis may not be easy, but a rapidly developing state of shock, and upper abdominal rigidity in cases of perforation of the lower oesophagus, are suggestive and call for *x*-ray examination by Gastrografin swallow. Only slightly less urgent is oversuture of a rupture of the trachea or bronchus. Malignant mediastinal emphysema may be relieved by needling parallel to the deep surface of the sternum, but cervical mediastinotomy or even a sternal split may be necessary. Tension pneumothorax is best treated with a wide-bore intercostal tube. Extensive subcutaneous emphysema may be relieved by "milking" the air through small incisions in the skin.

Frozen Poultry and Staphylococcal Food-poisoning

Two recent reports from Australia[1] and the U.S.A.[2] have suggested that frozen poultry meat may be a common source of staphylococcal enterotoxin food-poisoning. No figures for the incidence of staphylococcal food-poisoning, either in relation to other causal agents or in relation to the various foods responsible for outbreaks, were given by Anderson. Nevertheless, C. Genigeorgis and W. W. Sadler[2] quote G. M. Dack[3] as saying that in the years 1956 to 1961 poultry meat was the third most frequent food (after meat and bakery products) implicated in outbreaks of staphylococcal enterotoxin food-poisoning.

Records of food-poisoning incidents in the United Kingdom are compiled by the Public Health Laboratory Service from reports received from public health and hospital laboratories, and from notifications sent by medical officers of health to the Ministry of Health. A report is published annually in the *Bulletin of the Ministry of Health and Public Health Laboratory Service*. A study of these statistics up to 1966 does not suggest that staphylococcal food-poisoning and poultry meat have often been associated in the past. Thus not more than one or two outbreaks have been recorded in any one year. The number of incidents of staphylococcal food-poisoning reported every year has varied between 74 and 143 during the last decade, while the foods usually concerned were cold meat, such as ham and tongue, and sweet dishes, such as cakes and trifles.

One explanation for these apparent differences may be that both the methods of manufacture for poultry products and the national feeding habits in Australia and the U.S.A. are different from those in Britain. Thus the manufacture and distribution of cooked and frozen poultry rolls made up of compressed meat in plastic wrapping is commoner in the U.S.A., and Australia—though these have recently been imported and produced in Britain, and this may increase the likelihood of staphylococcal food-poisoning from poultry meat. Any food handled after cooking and before freezing may be contaminated with staphylococci from the hands of the workers and from the processing equipment. Whether the food remains safe will depend on the time between cooking, handling, and freezing and on the actions of the caterer or householder responsible for the preparation of food for the table. To produce enough toxin to cause food-poisoning staphylococci must grow in food, and every hour that the latter is exposed to room temperature increases the risk considerably. Moreover, washing the hands before handling food is no safeguard against the removal of staphylococci, which are well known to stick closely to the hands within the skin and in crevices and to defy all efforts at removal.[4]

Another question that has to be answered is whether the prevalence of coagulase-positive staphylococci could be due to their frequent occurrence in the birds themselves or in poultry workers, who then contaminate the environment. The broiler trade is troubled by staphylococcal sepsis in poultry, but little is known of the epidemiology of this disease or of its relation to the staphylococci carried by the workers in the intensive poultry farms and factories.

The multiplication of staphylococci on chicken meat before cooking could give rise to enterotoxin in situations inside the bird where heat penetration is poor, so that the toxin or perhaps even the organism itself would not be destroyed during cooking. But despite the heat resistance of enterotoxin, and despite the prevalence of *Staphylococcus aureus* in the slaughter-houses,[5] there are no reports of staphylococcal food-poisoning from meat contaminated when raw and subsequently eaten shortly after cooking. The survival of coagulase-positive staphylococci in lightly cooked meat or poultry could result in multiplication during long, slow cooling periods, yet it is the survival of salmonellae—and more particularly *Clostridium welchii*—which has given rise to many reported outbreaks of food-poisoning. The spores of *Cl. welchii* readily survive cooking temperatures, and germinate into actively growing bacilli in slowly cooling masses of meat and poultry, particularly those of large bulk. Thus at present codes of practice for caterers and housewives are under consideration. What is also badly needed are codes of practice for means and materials to clean equipment and working surfaces soiled by raw food materials, which bring food-poisoning organisms into the kitchen.

Neonatal Hirschsprung's Disease

G. C. FRASER,* M.B., F.R.C.S., F.R.C.S.ED.; A. W. WILKINSON,† CH.M., F.R.C.S., F.R.C.S.ED.

Brit. med. J., 1967, 3, 7-10

During the 18 years since Swenson and Bill (1948) first showed that Hirschsprung's disease could be cured by resection of the abnormally innervated distal segment of rectum and colon the clinical status of the disease has been transformed. Though the early onset of the clinical disturbance in Hirschsprung's disease has been repeatedly emphasized, the diagnosis was seldom made or the disease treated in the early days or weeks of life (Forshall, 1964). It seems likely that formerly many of the babies born with this disease died undiagnosed within a few weeks or months of birth. Bodian *et al.* (1949) and Eek and Knutrud (1962) estimated that the mortality in the first year was 50%. Most of these children probably died of gastroenteritis superimposed on the intestinal obstruction caused by the unrecognized aganglionosis.

Hirschsprung's disease has long been associated clinically with the picture of a young child with chronic or occasionally intermittent but severe constipation, accompanied by progressive distension of the abdomen and a striking failure to thrive. In the few survivors this led eventually to the classical form of the disease still described in many textbooks—a child with wasted limbs and a wizened face looking anxiously over the top of a huge belly packed with hard masses of faeces. Such children were often the survivors of regimens of repeated bowel washouts and constant purgation, and were poor subjects for radical surgical treatment.

The aganglionosis of Hirschsprung's disease affects the developing lower bowel at a very early stage (Bodian and Carter, 1963). That some degree of intestinal obstruction has been present for weeks before birth is indicated by the hypertrophy of the intestinal muscle of the transitional segment and the most distal part of the normally innervated segment. This hypertrophy may be readily seen at operation just after birth. With few exceptions the clinical features on which a diagnosis of Hirschsprung's disease can be made are evident within a day or two of birth (Forshall, 1964). One consequence of the increased interest in neonatal disorders during the past 10 years has been the recognition that Hirschsprung's disease is much commoner than had been suspected.

This report is based on a review of 54 babies (44 boys, 10 girls) who were admitted to the Hospital for Sick Children between 1 January 1958 and 31 December 1965, and who were under the age of 1 month on admission. The diagnosis of Hirschsprung's disease has been confirmed by histological evidence in every case. Only 36 patients survived their initial admission, a mortality of 33%. The birth weight was known in 53 patients (Fig. 1), of whom 22 weighed more than 3.5 kg. (7¾ lb.), and 6 (27%) of these died, whereas 11 died of the 31 who weighed less than 3.5 kg. (7¾ lb.) and 8 of the 12 who weighed less than 3 kg. (6½ lb.). Age on admission varied from a few hours to 28 days, but this did not seem to have any relation to mortality, because the average age on admission of babies who died was 12 days and of the survivors 10 days.

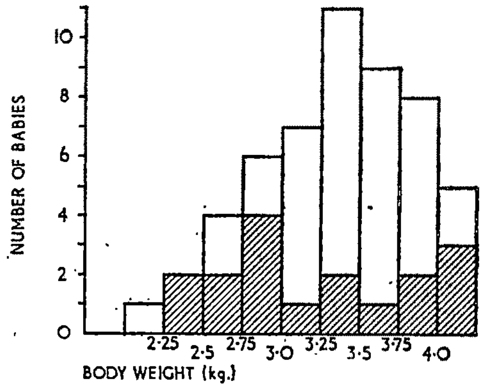

FIG. 1.—Birth weight in 53 cases. Cross-hatched squares indicate patients who died.

The lesions extended proximal to the pelvic colon ("long segment") in 12 babies, of whom 8 (66%) died, whereas of the 42 patients in whom only a short segment was involved 10 (24%) died.

Clinical Features

When Forshall (1964) reviewed a group of children of al ages with Hirschsprung's disease she found that four mai clinical features were common in the neonatal period—vomiting, abnormality of bowel habit, abdominal distension, an reluctance to feed. In addition to these features the genera appearance also may be characteristic. The face is thinne than normal and wrinkled; the skin looks dull and grey an feels limp even when the baby is only 2 or 3 days old an vomiting has not been so severe as to cause dehydration. T neonate with Hirschsprung's disease may have a worried frowning appearance, which, combined with thin featur makes the baby look like a little old man. Often the baby irritable and the head may be rolled from side to si Abdominal distension may hinder the normal respirat excursion, and breathing may be rapid and grunting character.

Vomiting was recorded in 53 cases (98%). Persist vomiting, especially when the vomitus was bile-stain usually led to prompt referral to hospital, but this did affect the mortality rate, because 7 died of the 23 patient whom vomiting began on the first day, and 11 died of the who began to vomit later (Fig. 2).

---

* Formerly Resident Assistant Surgeon, the Hospital for Sick Children, Great Ormond Street, London W.C.1. Present address: Department of Surgery, Health Centre for Children, Vancouver General Hospital, Vancouver, B.C., Canada.

† Nuffield Professor of Paediatric Surgery, the Institute of Child Health (University of London); Surgeon, the Hospital for Sick Children, Great Ormond Street, London W.C.1.

Abnormality of bowel habit was noted in 49 patients and was an even more common disturbance on the first day of life (28 cases) than was vomiting (Fig. 2). It was usually first manifest by the failure to pass normal meconium. Subsequently stools might be infrequent, abnormal in colour, loose, or offensive.

Abdominal distension was recorded in 51 patients (94%) and appeared in the first three days in 31 (60%) out of 51, most commonly on the second day of life (Fig. 2). The mortality was not closely related to the time of onset of distension.

Failure to progress is difficult to define, and its recognition may depend a good deal on the vigilance and experience of the nursing staff and the clinician. The main features are reluctance to feed or a poor performance during feeding, listlessness, irritability, and a failure to gain weight satisfactorily. This type of disturbance was found in 40 patients (74%) (Fig. 2), and the observation was often first made by the nursing staff, nearly always during the first week of life.

It is usually said that on rectal examination the anal canal and rectum feel narow and grip the finger. As the finger is withdrawn it may be followed by a forcible gush of flatus and liquid offensive pale faeces. These features are not always present, especially when the rectum has already been examined in this way on several occasions, and their absence does not exclude the diagnosis.

Confirmation of Diagnosis

So far the clinical features of the disease have been emphasized because the early diagnosis of Hirschsprung's disease in the neonatal period mainly depends on awareness of them and their recognition. Some support for this provisional diagnosis may come from a radiograph of the abdomen with the baby in the erect position, and in sufficiently fit babies it can be confirmed by *x*-ray examination after a barium enema. A radiograph taken with the baby erect will usually show the degree and distribution of gaseous distension of the intestine; further useful information may be obtained from a lateral erect exposure, since this often shows more clearly how far down into the colon and rectum the gaseous distension extends. In a neonate with a distended abdomen absence of gas from the pelvis, especially on an erect lateral radiograph, is suggestive of Hirschsprung's disease.

In the present series 27 patients were *x*-rayed after a barium enema, some in the first two or three days of life. The diagnosis of Hirschsprung's disease was correctly made in 24 instances, in one the appearances were equivocal, and in the remaining two patients the diagnosis was incorrect, but in both of them the rectum had been washed out before the barium examination. No complications were associated with the radiological examination in these 27 patients. The diagnosis may also be confirmed by histological examination of a biopsy specimen taken from the aganglionic bowel. Biopsy specimens were taken from the rectum in 21 patients in this series, of whom two died of peritonitis due to perforation during or soon after the biopsy was done.

Cause of Death

The causes of death of the 18 babies are shown in the Table. One (Case 5) was dead on arrival at the hospital and three (Cases 6, 7, and 11) were very ill when admitted. Some kind of severe infection occurred in all but one (Case 16), but in eight of these it was a direct consequence of the surgical treatment. In two patients (Cases 1 and 2) peritonitis was due to the bowel being perforated while the rectum and colon were being washed out, and in two others (Cases 3 and 4) peritonitis was secondary to perforation during or soon after diagnostic rectal biopsy. Five patients (Cases 5, 6, 7, 8, and 9) died of enterocolitis. One of these was dead on arrival at hospital with peritonitis due to perforation of the ascending colon secondary to enterocolitis. Two others (Cases 6 and 7) arrived already very ill with enterocolitis and survived colostomy for only a few hours. In two others (Cases 8 and 9) enterocolitis developed after the institution of a colostomy for the relief of low obstruction. Another child (Case 10) died of gangrene of the jejunum and ileum of uncertain cause 30 hours after an ileostomy had been made for relief of a long-segment obstruction.

A long segment of the bowel (more than the rectum and pelvic colon) was involved in 12 of the 54 patients of this series, of whom 8 died (67%), whereas for babies in whom only a short segment was involved the mortality was 24%. In five patients (Cases 11–15) a long segment of bowel was involved, the full extent of which was not recognized at the first operation. Repeated operations were needed for the relief of intestinal obstruction and were associated with infective complications; in four of these there were also obstructions due to adhesions. It may be very difficult to recognize exactly, by eye alone, the extent of the aganglionic segment at a primary laparotomy for relief of a neonatal intestinal obstruction. Whenever possible the diagnosis and the extent of the aganglionosis should be confirmed by the immediate

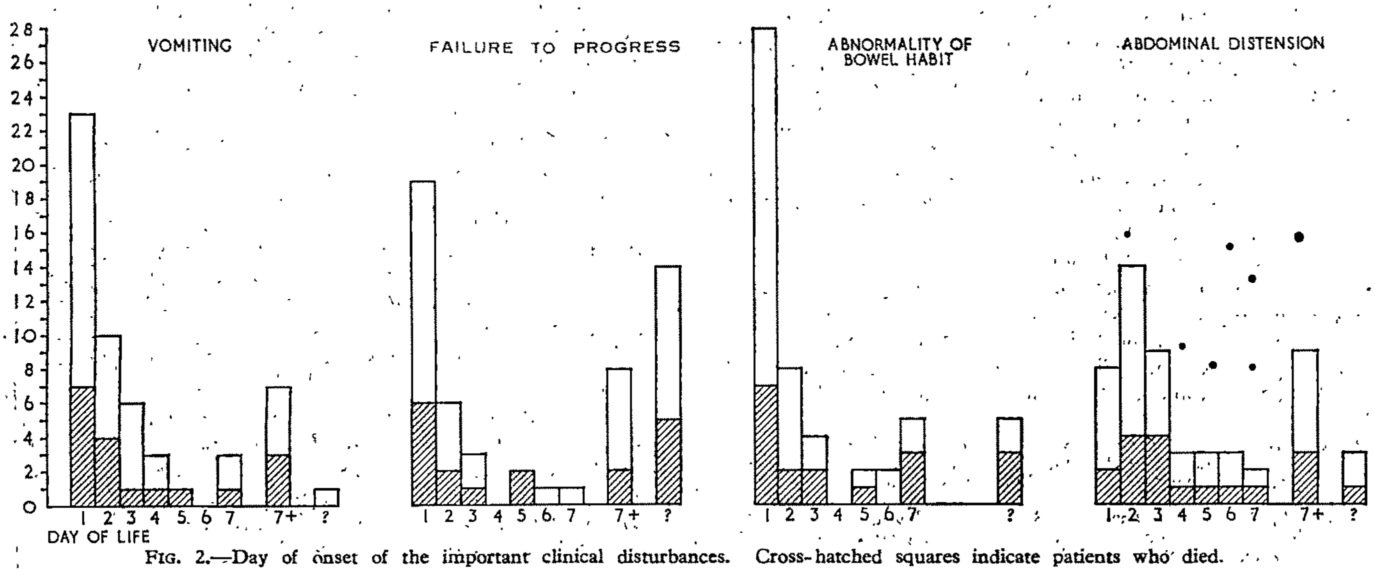

FIG. 2.—Day of onset of the important clinical disturbances. Cross-hatched squares indicate patients who died.

histological examination of a frozen section of a specimen from the bowel wall.

There were three mongols, of whom two died without any surgical treatment—one of bronchopneumonia due to aspiration of vomitus, and the other of cardiac failure. The third patient was treated conservatively for 30 days and then was subjected to a primary pull-through operation of the Soave type; after operation abdominal distension persisted except when relieved by bowel washouts per anum. This child died of cardiac failure at the age of 10 weeks, and necropsy showed a pelvic abscess and congenital defects.

Discussion

It is of the nature of Hirschsprung's disease that there is a high degree of intestinal obstruction from the time the bowel first develops in utero long before the baby is born. This is because the obstruction is due to the defective development of the nerve supply to the muscle coats of a varying length of the rectum and colon and very rarely of the small intestine (Swenson and Bill, 1948). Though in a few patients only a centimetre or two of the lowest part of the rectum may be aganglionic, and in such patients a satisfactory response may sometimes follow conservative treatment by repeated digital dilatation, the passage of rectal tubes, and rectal washouts, this response may be transient and the risks of perforation and water intoxication are well known. In those babies in whom the aganglionic segment extends above the lower two-thirds of the rectum it is unlikely that dilatation of the upper anal canal and lower rectum will be effective in relieving the obstruction. When the pelvic or more proximal parts of the colon are involved the narrow segment cannot be completely dilated, and bowel washouts are clearly useless and dangerous. A colostomy or ileostomy is essential for complete relief of the obstruction.

Details of Fatal Cases

Case No.	Sex	Age on Admission (Days)	Age at Death (Days)	Length of Segment	Cause of Death at Necropsy	Comments
1	M	3	15	Short	Peritonitis	Perforation during washout. Laparotomy; died 3 hours later
2	F	2	4	,,	,,	Perforation during washout. Colostomy; died 10 hours later
3	M	23	62	Long	Obliterative peritonitis	Perforation after rectal biopsy. Laparotomy, colostomy, ileostomy. 1 week later, small intestinal fistulae
4	M	8	21	,,	Peritonitis, bronchopneumonia	Ileostomy, perforation of rectal biopsy, peritonitis, laparotomy
5	M	5	5	Short	Enterocolitis, perforation of ascending colon, peritonitis	Dead on arrival
6	M	19	19	,,	Enterocolitis	Very ill on admission. Colostomy; died 5½ hours later
7	M	25	26	,,	Enterocolitis, necrosis of ileum	Very ill on admission. Peritonitis. Laparotomy, colostomy; died 8 hours later
8	M	8	17	,,	Peritonitis, enterocolitis	Gangrene of left iliac and transverse colostomies and colon
9	M	10	17	,,	Purulent colitis beyond colostomy, ? early enterocolitis above colostomy	Ill on admission. Colostomy sclerema 3rd to 5th postoperative days—subsided; sudden death on 7th day
10	M	2	4	Long	Gangrene of jejunum and ileum. ? Cause	Malrotation of midgut and Hirschsprung's disease to distal ileum; died 30 hours after ileostomy
11	M	14	20	,,	Septicaemia, multiple abscesses in lungs and heart	Admitted very ill after several operations elsewhere for "meconium obstruction." Ileostomy; died 8 hours later
12	M	1	50	,,	Multiple infections and abscesses	Colostomy on 12th day. Laparotomy 44th day for intestinal obstruction due to adhesions at biopsy site
13	M	27	76	,,	Multiple infections, dehydration	Ileostomy, rectal biopsy, laparotomy for obstruction due to adhesions. Repeated bouts of diarrhoea with parenteral therapy
14	M	3	67	,,	Septicaemia, lung abscesses, subacute intestinal obstruction	Original colostomy wrongly sited because of erroneous report on frozen section; repeated operations to resite colostomy and relieve adhesion obstructions
15	M	28	38	,,	Chronic peritonitis, perforated anterior duodenal ulcer	Colostomy 24 hours after admission, adhesion obstruction 4 days later. Laparotomy
16	M	12	37	Short	Cardiac failure, multiple anomalies	No surgical treatment. Mongol
17	M	24	48	,,	Bronchopneumonia, cardiac failure	No surgical treatment. Mongol
18	M	3	70	,,	Cardiac failure, pelvic abscess	Primary Soave rectosigmoidectomy; needed postoperative washouts. Mongol

In general the babies in this series were of normal size at birth. This is in contrast with the situation in atresia of the oesophagus or duodenum, in which about a quarter of the babies weigh less than 2.5 kg. (5½ lb.) (Waterston *et al.*, 1963; Young and Wilkinson, 1966), compared with only 3 (5.5%) in this series. It is of interest that only 10 out of 106 patients with meconium obstruction treated in this and another hospital weighed less than 2.5 kg. (5½ lb.) (Holsclaw *et al.*, 1965), a proportion not much different from that in the normal population. However, in meconium obstruction the mortality was higher (46%) in babies weighing 6 to 8 lb. (2.7 to 3.6 kg.). In this series of babies with Hirschsprung's disease there was not much variation in mortality rate with different birth weights. In an earlier report from this hospital Wyllie (1957) found the preoperative weights were below average for age, but this was because his patients were older and had failed to thrive. Only 33 of Wyllie's 157 patients were operated on in the first year of life.

Like Forshall (1964), we found few other congenital anomalies associated with Hirschsprung's disease, which in this way resembled meconium obstruction and was unlike oesophageal and duodenal atresia. Hofmann and Rehbein (1966), however, found other serious malformations in 17 (32%) of the 53 neonates in their series.

When persistent and detailed inquiry had been made clinical evidence of the disease during the first week of life was established in almost every child in this series. Vomiting (98%), abdominal distension (94%), and abnormal stools, constipation, or diarrhoea or both (98%) were the most important features and were usually present together. Though such disturbances might appear within a day or two of birth they were not invariable or progressive. Especially when only a very short segment of the rectum was involved, remission of the obstruction might follow digital rectal examination and the subsequent expulsion of gas and liquid faeces. In a few cases such a remission lasted several weeks or even months, but more often recurrent disturbances led to relief by operation. Hofmann and Rehbein (1966) found abdominal distension in all 53 of their neonates with Hirschsprung's disease and bilious vomiting in all but one, and that in 70% meconium had not been passed or had appeared in only small quantities. In the neonate episodes of vomiting of bile-stained fluid, especially if accompanied by abdominal distension, always justify the taking of a radiograph of the abdomen in the upright position to see if there is evidence of intestinal obstruction.

The best and safest way of confirming the clinical diagnosis is by radiological examination after a barium enema, provided that the bowel has not been washed out. Only in those babies whose general condition is too poor for radiological examination and who urgently require the decompression of their obstructed bowel should a colostomy be made without establishing the diagnosis; in these the barium-enema examination can be done a few days later. Rectal biopsy is difficult and dangerous in the neonate and may provide too little tissue for a sat-factory histological examination; it should be done only when the result of radiological examination is equivocal.

A third of the patients in this series died, a clear indication of the serious potentialities of Hirschsprung's disease. That such a high mortality should be found in a series of patients in whom the disease had been recognized within the first month of life adds weight to the former estimates (Bodian *et al.*, 1949; Eek and Knutrud, 1962) that 50% died in the first year of life.

The higher mortality in neonates has also been emphasized by Hofmann and Rehbein (1966): 15 of their 53 neonates died. They prefer to treat the condition by washouts and hot packs rather than by colostomy, to which they resorted only when conservative treatment failed. Only two of their patients died during conservative treatment and the remaining 22 survived subsequent resection of the aganglionic bowel. However, of the 31 in whom a colostomy had to be made, 8 died and 19 had a complicated course, and five more died subsequently after resection of the affected bowel.

It seems to us that when Hirschsprung's disease is diagnosed soon after birth the safest form of treatment is decompression of the obstructed bowel by a colostomy or ileostomy with as little delay as possible. Resection of the abnormally innervated segment of bowel should be delayed until the child is 1 year old or weighs 20 lb. (9.1 kg.).

It is not surprising that the mortality rate should be higher in the babies with the "long segment" type of disease, especially when the full extent of the lesion is not recognized at the first or subsequent operations to relieve the obstruction, and the colostomy or ileostomy is first made in aganglionic bowel.

In Hirschsprung's disease the term "abnormality of bowel habit" may imply either constipation or bouts of diarrhoea owing to the passage of faecal stained mucus round an impacted mass of faeces. In its most extreme form diarrhoea may be due to a sort of enterocolitis with mucosal ulceration and toxaemia that is often fatal. In another series of 47 patients with Hirschsprung's disease (Bill and Chapman, 1962) there were 24 with enterocolitis, of whom 21 were neonates and 8 died; though in this series enterocolitis did not occur after colostomy, it did in two of our patients (Cases 8 and 9). Bill and Chapman also found that patients who had once had enterocolitis were liable to its recurrence, especially after rectosigmoidectomy. Swenson and Davidson (1960) have reported a mortality rate of 33% in patients who were treated medically, but in those for whom a colostomy was made as soon as the disease was diagnosed the mortality rate was only 4%. It seems that the best way to prevent enterocolitis may be to make a colostomy as soon as the diagnosis of Hirschsprung's disease is made, but it must be recognized that this does not always provide complete protection from enterocolitis or prevent death from it.

Summary

Of 54 babies suffering from Hirschsprung's disease who were admitted within a month of birth, 18 (33%) died—5 of enterocolitis and 11 of other complications of the treatment; 2 mongols were not treated surgically.

The clinical disturbance associated with this form of congenital intestinal obstruction usually begins within the first two or three days after birth and is characterized by vomiting, abdominal distension, and abnormality of the bowel action. The clinical diagnosis was confirmed by *x*-ray examination after a barium enema in 24 out of 27 patients in this series; in one patient the appearances were equivocal and in two others the bowel had been washed out before the examination.

Neonatal intestinal obstruction due to Hirschsprung's disease should be relieved by a colostomy or ileostomy as soon as the diagnosis is established.

We are indebted to the late Mr. G. H. Macnab, Mr. D. J. Waterston, and Mr. H. H. Nixon for allowing us to include patients under their care in this survey.

Overinflation of the Lungs in Coal Miners

COLIN OGILVIE,* M.D., M.R.C.P.; KEITH BROWN,† M.D., M.R.C.P.; W. E. KEARNS,‡ M.B., CH.B.

Brit. med. J., 1967, 3, 10–14

Coal miners whose chest radiographs are normal tend to be more breathless than non-miners of the same age-group, but a pattern of dysfunction distinct from chronic non-industrial lung disease has not been observed.

The purpose of this report is to compare the results of lung-function tests in coal miners referred to a physiological laboratory because of unexplained dyspnoea with those obtained in a group of men suffering from chronic non-specific lung disease.

Patients

The first group consists of 17 miners (two from Yorkshire and 15 from West Lancashire coal fields) who were referred during 1963–6 to a lung-function laboratory providing a routine service for the region. In each case the miner had been referred by a consultant physician because physical and radiological examination had failed to reveal an adequate cause for his disability. These 17 cases represent the total number of miners referred to the laboratory in this way. Apart from clinical or radiological signs compatible with either chronic non-specific lung disease or pneumoconiosis, no cardiac or pulmonary cause for dyspnoea could be found in any of these patients. The only miners attending the laboratory during 1963–6 and excluded from this report were those referred for routine preoperative assessment or for the investigation of a disease not directly related to their occupation (mitral stenosis, bronchiectasis, bronchial carcinoma, or tuberculosis).

* Consultant Physician.
† Senior Medical Registrar.
‡ Medical Registrar.
Regional Cardiothoracic Centre, Broadgreen Hospital, Liverpool 14.

The occupational history and the clinical and radiological findings for the 17 miners are recorded in Table I. The average age was 57 years at the time of the investigation. Only five of the miners were still working underground, the remainder having left the mines an average of five years previously. The average duration of underground work was 32 years, 12 of the 17 miners having worked underground for 30 or more years. Of the five with less than 30 years underground, two had worked in other dusty occupations (26 years in a lead mine and seven years in a granite quarry respectively). The 17 miners all complained of either moderate (grade 2) or severe (grade 3) dyspnoea on effort (see Methods). The average duration of effort dyspnoea was six years. Five miners denied having any cough, while 12 complained of cough with a variable amount of sputum. Most of them stated that cough and dyspnoea started together, but none was sure about the total duration of cough.

* Plus 26 years in lead mines.
† Plus 7 years in granite quarry.

Physical signs of bronchitis were present in seven: expiratory wheeze was evident in five and coarse basal crepitations without wheeze in two others. The chest radiographs showed evidence of simple pneumoconiosis (categories 1–3) in eight cases and were clear in the remaining nine.

The second group consists of 15 male non-miners aged 50 and over referred to the laboratory as cases of chronic bronchitis and/or emphysema. These patients fulfilled the criteria required for a diagnosis of chronic non-specific lung disease: they were all suffering from chronic cough with sputum and/or persistent breathlessness *not* associated with localized lung disease of any kind, generalized specific infective diseases of the lungs, pneumoconiosis, generalized pulmonary fibrosis or granulomata, primary cardiovascular or renal disease, diseases of the chest wall, anaemia, or psychoneurosis (Ciba Guest Symposium, 1959). The 15 patients represent the total number of males aged 50 and over with chronic non-specific lung disease for whom adequate physiological data were available in the laboratory records.

Methods

The physiological techniques used are those described in previous publications (Ogilvie *et al.*, 1963), and include: (1) the subdivisions of the lung volume, including vital capacity (V.C.), functional residual capacity (F.R.C.), and residual volume (R.V.). F.R.C. and R.V. were measured by means of a closed-circuit helium method; (2) maximum voluntary ventilation at 80 respirations per minute (M.V.V.80); (3) maximum inspiratory and expiratory flow rates derived from the forced spirogram (M.I.F.R. and M.E.F.R.); (4) the forced expiratory volume in 1 second (F.E.V.$_1$); (5) arterial CO_2 tension by the rebreathing method (Pco_2); and (6) transfer factor for carbon monoxide (diffusing capacity, DL) by the single-breath technique.

The degree of dyspnoea was recorded for each miner before the physiological tests were carried out, according to the following grading:

Grade 1 (mild). Dyspnoea only on severe exertion such as running on the level or hurrying upstairs.

Grade 2 (moderate). Dyspnoea on one flight of stairs or walking up inclines. No dyspnoea when walking at a normal pace on level ground.

Grade 3 (severe). Dyspnoea when walking at a normal pace on level ground.

The normal values for lung volumes were predicted from the formula of Baldwin *et al.* (1948). The normal values for transfer factor were predicted from the formula of Ogilvie *et al.* (1957). The results in the two groups were also compared with those obtained in five normal men aged 50 and over studied in the same laboratory. These five men had been referred to general surgical clinics of the hospital from the same area as the

miners and were all free of symptoms, signs, and radiological evidence of respiratory disease.

Results

The vital statistics and physiological findings in the two groups are shown in Table II (miners) and Table III (non-specific lung disease) and the results of the physiological tests are compared in Figs. 1 to 6. The results obtained in the five normal subjects are recorded in Table IV and are also shown in Figs. 1 to 6.

Vital Statistics.—The mean age was 57 years (range 41–66) in the miners (group 1) and 58 years (range 50–70) in patients with chronic non-specific lung disease (group 2). The mean height was 67 in. (170 cm.) (range 63–72 in.; 160–183 cm.) and mean weight 151 lb. (68.4 kg.) (range 106–182 lb.; 48–82.5 kg.) in group 1, and 67 in. (170 cm.) (range 63–69 in.; 160–175 cm.) and 141 lb. (63.9 kg.) (range 109–187 lb.; 49.4–84.8 kg.) respectively in group 2.

Lung Volumes.—In Table V the mean values for V.C., R.V., and T.L.C. are expressed as the percentage of predicted normal according to the formula of Baldwin *et al.* (1948). Results are shown for the two groups in the present study and for the five normal subjects. According to the formula of Baldwin *et al.* and the findings in our own normal subjects, the residual volume is increased to about two and a half times the predicted normal in both groups, while the total lung capacity is increased by nearly one-third in the miners and by nearly one-quarter in the patients with non-specific lung disease (see also Figs. 2 and 3).

TABLE V.—*Means of Lung Volume Fractions and M.V.V. Expressed as Percentage of Predicted Normal (By the Formulae of Baldwin et al., 1948)*

	Normal Subjects	Group 1 (Coal)	Group 2 (N.S.L.D.)
Vital capacity	100%	78%	64%
Residual volume	106%	255%	256%
Total lung capacity	102%	132%	123%
Maximum voluntary ventilation ..	106%	80%	41%

Ventilatory Capacity.—The impairment of ventilatory capacity was considerably greater in group 2 than in group 1, the mean M.V.V. having nearly twice the value in the latter group (see Table V). This difference was due to the greater degree of expiratory airways obstruction in group 2: the mean M.I.F.R. was approximately the same in the two groups, but the mean M.E.F.R. in group 2 was less than one-quarter of the value obtained in group 1. The values for the M.I.F.R./M.E.F.R. ratio and for the F.E.V.$_1$ as percentage of vital capacity are compared for the two groups in Figs. 4 and 5. It will be noted that in 12 of the miners but in none of the other group, the M.I.F.R./M.E.F.R. ratio was within the normal range (0.5–1.5). Eight miners, but none in the other group, showed a normal F.E.V.$_1$ as percentage of V.C. (over 60%).

Transfer Factor (Diffusing Capacity).—The mean transfer factor as percentage of predicted normal was 99% in group 1 and 42% in group 2. Fourteen of the 16 miners had a normal transfer factor (over 75%) as compared with 3 of the 15 patients in group 2 (see Fig. 6).

P_{CO_2}.—This was measured by the rebreathing method in seven patients from each group. The mean value for P_{CO_2} in these patients was 36 mm. Hg in group 1 and 43 mm. Hg in group 2. The P_{CO_2} was elevated in one patient from group 1 and in two patients from group 2.

Discussion

In any study of disability in coal miners the mode of selection is clearly important. In the present investigation the miners had all been referred by a general practitioner to a consultant physician and thence to a regional pulmonary function laboratory because physical and radiological examination had not revealed an adequate cause for their disability. Inevitably the question of eligibility for pension arose in a number of these patients, and in several the possibility of a "compensation neurosis" had been raised by the referring physician. It is not surprising, therefore, that more than half of these miners had no physical signs of bronchitis nor any radiological evidence of dust in the lungs and that only two (Cases 4 and 5) were in receipt of a pension for pneumoconiosis.

This group of miners had certain other features in common, less obviously related to the method of selection. Fifteen of the 17 were over the age of 50 and 12 had left the mines several years previous to the investigation. Twelve of the 17 had spent 30 years or more underground and, of the remaining five, two had been engaged in other forms of dusty work. Finally, they all showed an increase in residual volume, total lung capacity, and R.V./T.L.C.% comparable to that observed in patients with chronic non-specific lung disease but without a commensurate degree of expiratory airways obstruction or impairment of the transfer factor.

Several authors (Gilson and Hugh-Jones, 1955; Carpenter *et al.*, 1956; Higgins *et al.*, 1956; Leathart, 1959) have found that miners with normal chest radiographs have a poorer M.V.V. than those whose films show simple pneumoconiosis. Furthermore, Gilson and Hugh-Jones (1955) reported a close correlation between M.V.V. and dyspnoea in coal miners, but when a group in hospital was studied the correlation between R.V./T.L.C.% and dyspnoea was almost as good. In Fig. 7 M.V.V. has been plotted against R.V. for the miners in the present study and the grade of dyspnoea is indicated for each case. The eight miners with simple pneumoconiosis tend to have a higher M.V.V. and smaller residual volume (mean M.V.V. 80 l./min.; mean R.V. 3.3 l.) than the miners with clear films (mean M.V.V. 50 l./min.; mean R.V. 4.8 l.). Moreover, the grade of dyspnoea in these eight miners (grade 2) was less than in seven of the nine with clear films (grade 3). There appears, therefore, to be some relation between dyspnoea on the one hand and a low M.V.V. with increased residual volume on the other, but this relation is not necessarily a causal one, for there are many other variables of lung function which have not been measured in the present study. For example, uneven distribution of inspired gas (Gilson and Hugh-Jones, 1955), disturbances of the mechanical properties of the lungs (Leathart, 1959), and an increased alveolar-arterial Po$_2$ difference (Brasseur, 1963) have all been reported in coal miners.

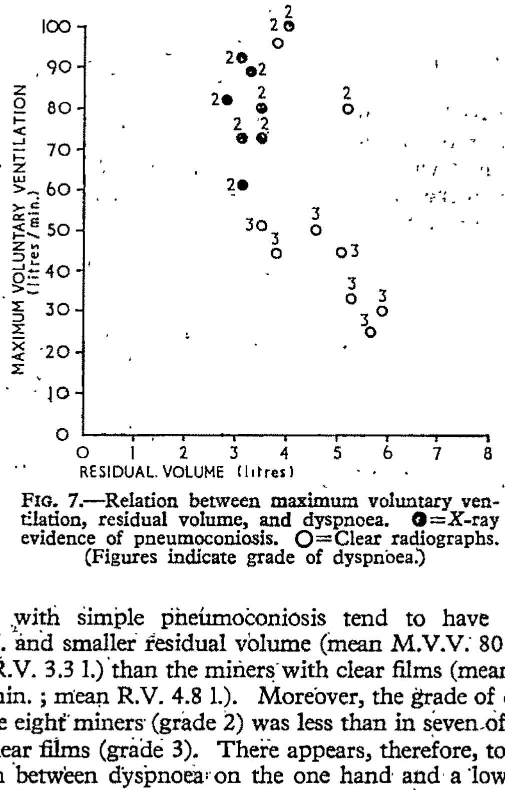

FIG. 7.—Relation between maximum voluntary ventilation, residual volume, and dyspnoea. ● = X-ray evidence of pneumoconiosis. ○ = Clear radiographs. (Figures indicate grade of dyspnoea.)

Carpenter *et al.* (1956) have suggested that the lower values for M.V.V. found in miners with clear films than in those with simple pneumoconiosis might be due to generalized emphysema in the former group, and Leathart (1959) supported this view. The finding of an increased residual volume among such miners in the present study is also in keeping with this suggestion. A possible explanation for this paradox has been offered by Rappaport (1966), who suggested that emphysema could mask the shadows cast by dust in the lungs. If emphysema is the cause of the increased residual volume found among the miners in the present study, then its physiological manifestations differ from those reported by Fletcher *et al.* (1963) for patients with primary emphysema. Fletcher's patients showed an increase in residual volume and R.V./T.L.C.% comparable to that found among the miners in the present series, but in addition there was severe airways obstruction and impairment of the transfer factor.

In their account of the pathogenesis of focal emphysema due to coal dust, Heppelston and Leopold (1961) pointed out that, initially, disruption of the alveoli is not a feature of this condition. Moreover, the bronchial smooth muscle is atrophic or absent and expiratory contraction of the bronchioles is diminished or abolished. Heppleston and Leopold attribute the alveolar dilatation to inspiratory traction upon the alveoli surrounding the deposits of dust rather than to expiratory airway obstruction. In the present investigation the finding among the coal miners of an increased residual volume with relatively less evidence of expiratory airway obstruction or impairment of gas transfer is compatible with Heppleston and Leopold's observations in focal emphysema. However, a normal transfer factor does not necessarily exclude alveolar destruction, and no conclusions can be drawn regarding the anatomical significance of our physiological findings. It is clear that a careful necropsy examination of the lungs of miners in whom physiological tests have been done during life is needed.

Summary

The physiological findings in 17 coal miners referred to a pulmonary function laboratory because of unexplained dyspnoea are compared with the findings in 15 patients referred with chronic non-specific lung disease and five normal subjects of the same age group.

The two groups of patients showed a comparable increase in residual volume, total lung capacity, and R.V./T.L.C.%, but expiratory airways obstruction and impairment of gas transfer were considerably less in the group of miners than in the patients with chronic non-specific lung disease.

The increase in residual volume was greater in the miners with clear radiographs than in those with simple pneumoconiosis. The increase in residual volume was also greater in those with a reduced M.V.V. and a high grade of dyspnoea, but it could still be detected in breathless miners with a normal M.V.V. and no evidence of expiratory airways obstruction.

It is suggested that the physiological findings in this group of miners are compatible with some of the reported pathological features of focal emphysema due to coal dust, but no conclusions can be drawn until necropsy studies are available for miners investigated during life.

We are indebted to the technical staff of the regional pulmonary function laboratory, Broadgreen Hospital, for their assistance in carrying out the tests reported in this paper; to Dr. James Carmichael, who read the chest radiographs; and to the consultant physicians who referred the patients for investigation. We are especially grateful to Dr. James MacArthur for his help and encouragement.

Psychiatric Study of a Consecutive Series of 34 Patients with Ulcerative Colitis*

FRED FELDMAN, M.D.; DAVID CANTOR, M.D.; SIDNEY SOLL, M.D.; WILLIAM BACHRACH, M.D.

Brit. med. J., 1967, **3**, 14–17

The purpose of this study is to evaluate the role of psychiatric factors in the causation of ulcerative colitis by survey of a fairly long unselected series. Ulcerative colitis is still one of the most enigmatic of diseases, despite its position, paradoxically, as the "classic" psychosomatic illness. Its cause is believed by most gastroenterologists to be unknown, yet a large number of reports by psychiatrists discuss it as an unquestionably psychosomatic illness. The studies by physicians and surgeons of such medical factors as cause, course, complications, and drug treatment have been for the most part cautious, uncertain, and qualified (Crohn and Yarnis, 1951; Michener *et al.*, 1961; Hijmans and Enzer, 1962; Korelitz *et al.*, 1962; Edwards and Truelove, 1963, 1964; Rhodes and Kirsner, 1965). On the other hand, reports by psychiatrists of much smaller series (Engel, 1961; Finch and Hess, 1962; Fullerton *et al.*, 1962; Powles, 1964), sometimes random and unselected, have used such terms as "constantly show severe psychopathology," "uniformly show pathology," "in every case," and "the evidence is overwhelming, incontrovertible."

We are aware that psychiatrists recognize that the disease is one which may be multifactorial in origin, and that some of them regard the psychogenic component as only one factor out of many. Nevertheless, the presence of severe psychopathic disease is so consistently described that the impression is gained from leading psychiatric papers that an emotional component is necessary for the condition to exist. Both sophisticated psychiatric readers and general physicians seem to derive this notion from the psychiatric literature. One of the papers cited above (Fullerton *et al.*, 1962), for example, stated specifically that ulcerative colitis "represented a morbid grief reaction," and other papers circuitously or directly imply that emotional conflicts are a requisite though perhaps only partial cause.

---

* From the Department of Medicine and Department of Psychiatry, Cedars-Sinai Medical Center, Mount Sinai Division, Los Angeles, California.

The concept of "psychosomatic disease" has become a blurred one, and the term is used in three different ways:

(1) The "true" or "strict" psychosomatic diseases are those which *must* have a psychogenic component as part of the cause, or they cannot exist. The usual lists of "true psychosomatic illness" include duodenal ulcer, ulcerative colitis, hypertension, asthma, and neurodermatitis.

(2) Illnesses which appear physical in origin but may be exacerbated, triggered, or hastened by psychogenic factors (one might postulate heart disease in this category) would be regarded as not "truly psychogenic" illnesses but ones influenced by psychophysiological factors. Some physicians feel that the diseases listed under paragraph (1) above may often belong only to this second level, and that no true psychosomatic disease has as yet been verified.

(3) Illnesses whose cause and physical pathology are at present unknown—for example, most headaches, other pains—may be designated as "possibly psychosomatic." No proof exists.

The psychosomatic literature is often vague and confusing in its criteria for validating the psychogenic component, and thus proving it an indispensable element.

We are suggesting seven criteria in an attempt to summarize all indices used by psychiatrists to prove that a psychosomatic disease may exist. The seven criteria are: (1) a characteristic personality disorder of moderately severe to severe degree, or other definite psychiatric diagnosis; (2) a clearly emotional precipitating factor, chronologically related to the illness; (3) general stress, not necessarily symbolically related to the illness but perhaps cumulative; (4) basic emotional problems of long or short duration, with significant background features symbolically related to the illness; (5) alternation of symptoms, or syndrome shift; (6) characteristic patterns of illness in the life history; and (7) efficacy of psychotherapy.

Material

Thirty-four patients with ulcerative colitis were studied. Every known patient with ulcerative colitis admitted to the gastroenterology service between August 1964 and June 1966 was included.

Tables I and II list age group, sex, severity of disease, number of crises, and patients who have been treated psychiatrically.

TABLE I.—*Age Groups and Sex Distributions of 34 Ulcerative Colitis Patients*

Age Group	No. of Patients	Males	Females
10–20	9	2	7
21–30	10	4	6
31–40	8	5	3
41–50	5	5	—
51–60	1	—	1
61–70	1	1	—
Total	34	17	17

TABLE II.—*Other Clinical Data on 34 Ulcerative Colitis Patients*

Severity of disease	Mild	8
	Moderate	12
	Severe	14
No. of crises	1	15
	2	6
	More than 2	13
Response to medical treatment	Able to function normally	19
	Function normally but frequent visits to doctors	6
	Not satisfactory functioning	5
	Not known	4
No of patients with ileostomy		5
No. of patients who received psychiatric treatment		7

Two types of "control" groups were used. The first can be regarded as a control group only in the loosest sense, since it consisted of the general population, divided into normal and abnormal according to arbitrary criteria. The second control group comprised 74 patients. These were the first 74 consecutive patients admitted to the gastroenterology service while the study on ulcerative colitis was in process. No patients with large-intestine disease or regional enteritis were included.

Method

The team members consisted of a psychiatrist, a physician, and two gastroenterologists, one of whom was a Fellow in Psychosomatic Medicine. All four have had a long-standing interest in psychosomatic disease. (The psychiatrist is also a psychoanalyst, and a member of the American Psychoanalytic Association.)

Each patient first had two standard psychiatric interviews, of the free-association type, but eventually including a discussion of sufficient current and past material to yield data for scoring about 65 variables considered salient for personality evaluation. The first interview usually lasted two to three hours, and was conducted by the Fellow. He then reported his findings to the team in detail. The team, including the psychiatrist plus the Fellow and one of the other physicians, then conducted the second interview, which lasted about an hour. Subsequently, the team, including the psychiatrist, almost always saw the patient a second time, and then as often as possible during the stay in hospital. The Fellow continued to see each patient every day, and reported to the team twice a week. The minimum amount of psychiatric time spent with and discussing each patient was five to six hours, and the average 10 to 12 hours. In some cases the time spent was longer, since, for example, three patients remained in the hospital several months.

The psychiatric evaluation took into consideration all the descriptive and dynamic variables which a complete evaluation requires. Among them were symptoms, cognition, ego strengths, defensiveness, acting out, dependence, external problems, attitude toward illness, past history, anxiety, depression, personality type, background, parents, role reversal, siblings, psychosomatic relationships, and many others. All 65 variables were scored in every case, on a 1 to 5 basis, as explained below. As noted above, the scoring for the seven criteria was undertaken cautiously. Broad limits for "normality" were used. The criteria for placing a patient in the "predominantly normal," "normal aggressive," or "normal passive" groups were: (1) no moderately severe or severe personality disorders; (2) average or better ego strengths in the great majority of the 14 categories of ego strengths in the inventory; (3) no severe emotional problems or conflicts which would have required psychotherapy were it not for the physical illness; (4) no diagnosis of psychosis, impulse disorder, or moderate to severe psychoneurosis or depression; (5) evidence of constructive handling of life's anxieties and problems; and (6) no significant patterns of hypochondriasis or incapacity due to unexplained illness of any sort.

The entire process by which the decision about normality was made is too compendious to describe. However, it was thought to be so important that a 200-page handbook has been written, and used, to evaluate all of the 65 variables in the inventory. Criteria for scoring each variable as 1, 2, 3, 4, or 5 were given.

Each patient was diagnosed as "normal" or "abnormal" in each category of the protocol. "Normal" was scored as 3, 4, or 5, "abnormal" as 1 or 2. A normal distribution curve was used (Fig. 1). This curve refers to the general population—that is, an arbitrary assumption has been made that approximately 70% of the general population are "normal" and 30%

definitely "abnormal." We recognize the danger that such a decision may appear uncompromising and high-handed. We tried to take into consideration, for each patient, a comparison not only with the general population but also with the patient's cultural group.

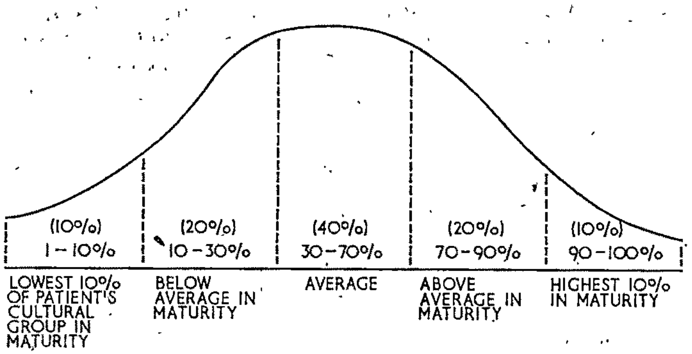

FIG. 1.—Normal distribution curve.

The final designation of normality or abnormality was made by discussion among all four investigators. No patient was placed in the normal group unless all four agreed.

Results in Ulcerative Colitis Patients

Personality Types and Psychiatric Illness.—Twenty-nine of the patients were regarded as essentially "normal" and five as "abnormal." The five abnormal personality types included one or more of the following character disorders to a significant degree: inadequate, infantile, passive, schizoid, depressive, or dependent. There were among the "normal" personalities mild to moderate personality characteristics in this incidence: passive-dependent, 8; passive-aggressive, 5; anxious, 1. Fifteen were classed as predominantly normal—that is, to have no or very mild character disorders. There was one psychopathic personality who was also diagnosed as "schizoid." There were no psychoses, severe psychoneuroses, or severe depressions.

Fig. 2 shows the data given above, and also the following precipitating factors and stresses.

Precipitating Factors and Chronological Relations.—In only 4 out of the 34 cases was a significant precipitating factor thought to have occurred close in time to the first attack of ulcerative colitis. In three cases there was a possible substantial emotional conflict. In 15 cases a moderately eventful emotional factor was present within six months of a *relapse* of the disease but not before its first occurrence. It must be noted that by this time almost every patient had been alerted to the "probable" emotional origin of ulcerative colitis, and was therefore often impressionable to what might otherwise be considered to be normal events. (*a*) No instances of extreme *separation anxiety* were found. No specific symbolic *separation factors* were regarded as pivotal. (*b*) There were no instances where fear of taking *forward steps* in career or marriage seemed crucial. In general, all 29 classed as "normal" were thought to have handled adolescent or adult responsibilities fairly well. There appeared to be no excessive fear that outgoing or aggressive behaviour was dangerous or destructive, and many of them had played football and other sports, had "hit back" when hurt, and had shown an ability to reach out to forward their ambitions when necessary. In general, then, our cases did not show the consistent presence of important precipitating factors.

General Conscious Stress, Not Necessarily Symbolically Related to the Illness, but Perhaps Cumulative.—This factor is difficult to evaluate, since every sensitive human being is aware of stress. We tried to be realistic in evaluating the degree of stress in a patient's life, and regarded as significant any degree of conflict beyond the average. In only five instances was a moderate to severe degree of stress present before the onset of the first attack. There were no other instances of "extreme stress" in the other 33 patients in the approximately five years preceding onset of the illness. In nine cases a moderate to moderately severe degree of stress was present before a *relapse.* There were no cases of *extreme* stress before relapses.

Basic or Nuclear Emotional Problems, of Long or Short Duration, with Significant Background Features, Symbolically or Unconsciously Related to the Illness.—There were 14 cases in which the total background, or dynamic, factors were such as to suggest the "possibility" of nuclear conflicts which might express themselves in somatic illness, if such conversion is thought possible. In no case was it felt that any of the possible nuclear conflicts showed a demonstrable symbolic relation to the ulcerative colitis. There were no instances of severe *role reversal* in childhood, for example. The extent of unusual aggressiveness in mothers and passivity in fathers was about average for the population. The type of "helplessness" described by Engel (1954, 1955, 1958) was considered to be present only as secondary to the illness itself. There was often no helplessness even in seriously ill patients. We found no notable prevalence of problems of bowel training or bowel preoccupation in the family.

Alternation of Symptoms, or Syndrome Shift.—No alternation of either psychiatric or physical symptoms with the ulcerative colitis was encountered in the patients' history or in their hospital course. *Headaches* were a complaint in six cases, but without significant reference to the severity of the ulcerative colitis symptoms. Mild to moderate *depression* was present in four cases; there was no alternation with the symptoms of colitis; if anything, the depression was severe only when the colitis symptoms were most severe.

Characteristic Patterns of Illness in the Life History.—There were a number of cases of mild hypochondriasis, but none was outstanding. Most of the patients had had relative freedom from physical and psychiatric illness.

Efficacy of Psychotherapy.—Of the 34 patients seven had undergone fairly extensive psychiatric treatment lasting from several months to eight years. In three cases it had aided the patients' adjustment to the disease, but in none did it have an appreciable effect on the course of the illness.

Results in Control Group

The patients in this group were as carefully examined and followed as were the patients with ulcerative colitis. The results are not described in detail here, but are compared with those of the ulcerative colitis patients in Fig. 2. In general, the control patients showed as much psychopathology as, or more than, the ulcerative colitis cases.

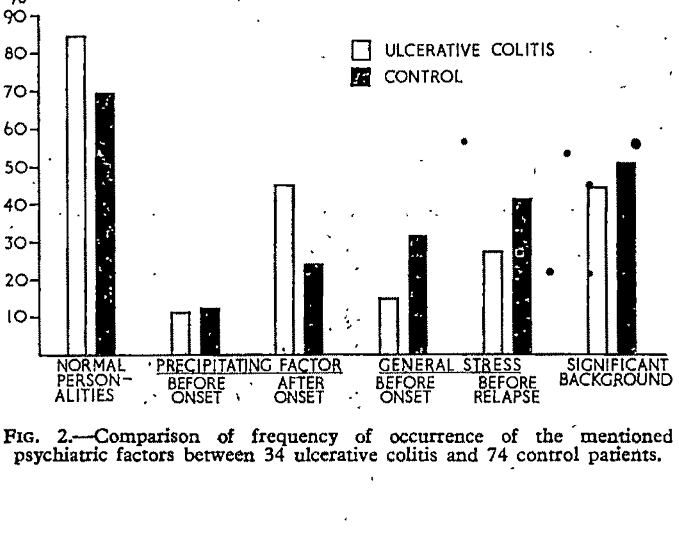

FIG. 2.—Comparison of frequency of occurrence of the mentioned psychiatric factors between 34 ulcerative colitis and 74 control patients.

Discussion

Essentially the 34 ulcerative colitis patients fall within the distribution of "normality" in our society as we have defined it. The question of whether or not an accurate psychiatric appraisal can be made in one or two interviews, plus observation of the patient for a brief period in the hospital, is a valid one. It may be answered in part by the experience of the psychiatrist in another situation where a similar type of evaluation proved successful. This involved eight years of experience in a low-cost psychoanalytic clinic, where patients were screened in one or two interviews by a team of two to four psychiatrists.

Our review of the literature became so lengthy that we have included it in a companion paper. In general, we found that our results were different from those of most psychiatrists but similar to those of the gastroenterologists.

Of approximately 300 reports a year in the world literature we estimate that about 10% are devoted primarily to the psychogenic aspects, another 20 to 30% mention psychiatric factors with uncertainty or partial acceptance, and the remaining 60 to 70% omit psychiatric aspects almost completely. Most of the psychiatric reports are subject to several criticisms. Many of them deal with only one or two patients analysed at great length, little attention being paid to the medical irregularities of the illness. Many of the studies are retrospective (Daniels *et al.*, 1962 ; Fullerton *et al.*, 1962 ; Langford, 1964), or deal with relatively large groups gathered from questionaries and not evaluated personally by the team (Weinstock, 1962). Many studies are of cases selected by other physicians and then referred to psychiatrists (Mohr, 1960 ; Sperling, 1960). In other instances no controls were used, or the criteria for emotional evaluation were not given, or cases were reported only if they had been in treatment (O'Connor *et al.*, 1964).

So far as we can tell, our series of 34 is the first in which a relatively large, consecutive, and unselected group of cases has been studied by the same team, using the same methods, planned in advance. There are two other studies in the literature, of about the same length, which may be comparable (Wittkower, 1938 ; Langford, 1964). Their cases were investigated less intensively than ours.

In our review we encountered the phenomenon of what might be called the innocent acceptance of previous reports (McDermott, 1966). Another observation is that in some of the papers written by teams of gastroenterologists and psychiatrists (or psychologists) there appears to be a split in the reactions of the two groups about the patients (Ehrenpreis *et al.*, 1960).

Summary and Conclusions

Thirty-four consecutive unselected cases of ulcerative colitis have been studied psychiatrically. They appeared to present essentially the usual distribution of emotional problems to be expected in a group of that size. This statement must be modified by several qualifications, particularly the difficulty in assessing deeper problems with our type of interviews. As many as possible of the emotional factors relating to psychosomatic illness mentioned in the psychiatric literature were found not to apply in any significant degree. Our series is small and no definitive conclusions are drawn. We do, however, raise the question whether the disease should be regarded as "psychosomatic."

Our results are presented with concern and caution, since large philosophical questions are raised. These questions concern: (1) the concept of "normality" and our recognition that the assumption of 70% "normality" is open to criticism ; (2) the reliability of diagnostic criteria in psychiatry as compared with other fields of medicine ; (3) the symbolic significance of diarrhoea in ulcerative colitis, taking into consideration the fact that the motility of the bowel in ulcerative colitis patients is different from that found in "functional" colonic disorders (Almy *et al.*, 1949 ; Chaudhary and Truelove, 1961) ; and (4) the central problem of whether primary psychosomatic disease exists, and, if so, how it can be explained.

Pernicious Anaemia among Asians in Singapore

F. J. JAYARATNAM,* M.B., B.S., M.R.A.C.P. ; CHENG SIANG, SEAH,† M.D., M.R.C.P.ED.
J. L. DA COSTA,‡ M.B., B.S., M.R.C.P.ED., M.R.C.P.GLASG.
KHENG-KHOO, TAN,§ M.B., B.S., D.C.P., DIP.PATH., M.C.PATH. ; W. O'BRIEN,|| O.B.E., M.D., F.R.C.P.

Brit. med. J., 1967, 3, 18–20

In an investigation of 40 consecutive cases of megaloblastic anaemia admitted to the Medical Unit, Thomson Road General Hospital, Singapore, from mid-1962 until the end of 1965, six patients (four Chinese and two Indians) were found to fulfil all the criteria for a diagnosis of pernicious anaemia. All six had megaloblastic marrows, histamine-fast (maximal stimulation) achlorhydria, very low serum vitamin-B$_{12}$ levels, and an inability to absorb this vitamin orally, this inability being corrected by the addition of intrinsic factor. These cases are worth reporting, because pernicious anaemia has not hitherto been reported in Singapore and Malaysia, and also because of the paucity of reports of pernicious anaemia in Chinese and Indians.

Methods

The following investigations were carried out:

Haematological investigations included an estimation of the haemoglobin, total red and white cell, platelet, and reticulocyte counts, packed cell volume, mean corpuscular volume, mean corpuscular haemoglobin concentration, and examination of smears of the peripheral blood film and bone marrow. Serum vitamin B$_{12}$ and folic acid assays were carried out in the Hammersmith Postgraduate Medical School, London, through the courtesy of Professor D. L. Mollin. The method of vitamin-B$_{12}$ assay was that of Mollin and Ross (1957), using *Euglena gracilis*, while folic acid assays were carried out by employing *Lactobacillus casei* as a test organism (Waters and Mollin, 1961). An augmented histamine test meal examination was carried out as described by Kay (1953), and the Crosby capsule (Crosby and Kugler, 1957) was used for gastric biopsies.

In order not to miss other causes of vitamin-B$_{12}$ deficiency, the following investigations were also made: a careful dietary survey by a qualified dietitian, examination of stools for ova, cultures of stools, a barium-meal examination with follow-through, a xylose-tolerance test, and an estimation of the total fat content of stools for five consecutive days while on a diet containing 75 g. of fat a day.

When all preliminary investigations were completed, a therapeutic trial with vitamin B$_{12}$ was carried out in each case ; 10 μg. of vitamin B$_{12}$ was administered intramuscularly once weekly, the haematological response being charted by means of daily reticulocyte counts and weekly haemoglobin estimations, total red cell counts, and packed cell volumes.

Finally, the absorption of vitamin B$_{12}$ with and without the simultaneous administration of hog intrinsic factor was estimated by Schilling's (1953) method, using ^{58}Co-labelled vitamin B$_{12}$. In four patients vitamin-B$_{12}$ absorption with and without the simultaneous administration of intrinsic factor was also determined by the modified faecal excretion technique of Mollin *et al.* (1957) and by a scintillation count over the liver one week after the administration of the test dose of vitamin B$_{12}$ (Glass *et al.*, 1954).

Clinical Findings

Of the six patients four were Chinese and two were Tamils, immigrants from the South of India. Four were males and two were females, their ages varying from 50 to 68 years (Table I). Their modes of presentation varied: three complained of pallor and two of progressive breathlessness on exertion ; one complained of fever and diarrhoea for a few days and had not noticed his pallor ; and two complained of paraesthesiae, weakness of both legs, and unsteadiness of gait. Though three patients had excessive melanotic pigmentation over the face, hands, and soles, only one had noticed this pigmentation.

TABLE I.—*History and Clinical Findings*

Case No.	Race	Age	Sex	Complaints	Physical Findings
1	Indian (Tamil)	62	M	Melanotic pigmentation. Paraesthesiae in lower limbs. Sore tongue	Pallor. Glossitis. Melanotic pigmentation. Subacute combined degeneration of cord
2	Chinese	68	F	Pallor. Exertional dyspnoea	Pallor. Loss of vibration sense in lower limbs
3	Indian (Tamil)	54	M	Fever. Diarrhoea	Pallor. Melanotic pigmentation
4	Chinese	68	M	Anorexia. Pallor	Pallor. Melanotic pigmentation
5	,,	64	F	Exertional dyspnoea	Pallor
6	,,	50	M	General weakness. Pallor. Paraesthesiae in lower limbs	Pallor. Glossitis. Subacute combined degeneration of cord

Physical examination revealed the presence of moderately severe pallor of the conjunctivae and mucous membranes in all the patients. Three had an even melanotic pigmentation involving the face, particularly the circumoral area, the dorsum and palms of the hands, and the dorsum and soles of the feet. Glossitis was present in only two patients. Abnormal neurological signs were confined to three: an Indian (Case 1) and a Chinese (Case 6) had the classical signs of subacute combined degeneration of the cord in the lower limbs, and a Chinese (Case 2) had loss of vibration sense in the lower limbs.

Results of Investigations

These results are summarized in Table II. All the patients were anaemic (haemoglobin varied from 4.3 to 6.2 g./100 ml.) with macrocytic well-haemoglobinized red cells, megaloblastic bone marrows, and histamine-fast achlorhydria (Kay, 1953). Serum vitamin-B$_{12}$ levels before treatment were very low, varying from 10 to 40 μμg./ml. The serum folic acid levels, which were estimated simultaneously, were normal, and varied from 4.5 to 25.1 mμg./ml.

Gastric biopsies in five patients revealed severe atrophic gastritis ; the sixth patient refused consent for a biopsy. The results of the Schilling tests confirmed the diagnosis of pernicious anaemia in these patients. Absorption of vitamin B$_{12}$

was negligible in the absence of intrinsic factor, but was enhanced to a normal range by the simultaneous administration of intrinsic factor. None of the patients had any renal dysfunction which would have rendered the Schilling test unreliable. However, in four patients the absorption of ^{58}Co-labelled vitamin B_{12} was also determined by the faecal excretion technique of Mollin *et al.* (1957) and the hepatic uptake method of Glass *et al.* (1954), and the results obtained confirmed those obtained by Schilling's method. Finally no evidence of malabsorption was found in any of the patients. Microscopical examinations and cultures of the stools, fat content of the stools, xylose-absorption tests, and barium studies were all normal.

Response to Vitamin-B_{12} Therapy

After completing investigations, 10 µg. of vitamin B_{12} was administered intramuscularly weekly. All six patients responded with a reticulocytosis, the peak reticulocyte count varying from 14 to 23% and occurring on the fifth to the sixth day after the first dose of vitamin B_{12}. Two patients (Cases 1 and 6) who presented with subacute combined degeneration of the cord improved rapidly with specific therapy. The other four remained well on maintenance vitamin B_{12} therapy.

Discussion

Pernicious anaemia of the Addisonian type is probably rare among Asians, though reports of its occurrence can be found in the literature. Friedlander (1934) discussed the racial incidence of the disorder and noted its rarity in Negroes and even in the dark-skinned white races—for example, Italians and Greeks. Das Gupta and Chatterjea (1951) reviewed Indian publications and found a few reports (Taylor and Chitkara, 1940; Chhuttani, 1948); in the same article they described three well-documented cases of megaloblastic erythropoiesis, achlorhydria, and subacute combined degeneration of the cord improving after treatment with crude liver extract. These three patients, they stated, were found "after a careful examination of a very large number of Indian patients with macrocytic anaemia during a period of 15 years." Since then a few more instances have been added in publications from India; Konar (1951) and Misra and Singh (1961) each described one case.

The paucity of reports (in English) of pernicious anaemia in Chinese patients is even more pronounced. Morris (1929) found six cases in the hospital records of Central and North China, but these were not documented, and in his own experience there were no proved cases. Yang and Keefer (1931) reported on two cases of pernicious anaemia in Chinese living in the U.S.A. Both were cases of Minot's and apparently were typical. Schwartz and Rappolt (1945) described three Chinese who suffered from this condition in Chicago; the diagnosis was made on clinical grounds and a satisfactory response to administration of liver extract.

The evidence thus far does indicate that pernicious anaemia of the Addisonian type is uncommon among Asians. This, however, may not be a true evaluation for the future. It remains to be seen whether an increasing awareness of its occurrence and the availability of the more recent tools of investigation—for example, radioactive vitamin B_{12} and its absorption tests—will alter the present concept of its rarity among Asians.

The six cases described in this paper formed part of the group of 40 consecutive cases of megaloblastic anaemia mentioned above. Of the remaining 34 patients, 30 were found to have nutritional folic-acid deficiency, two were vegans suffering from nutritional vitamin-B_{12} deficiency, and two had a haemolytic anaemia complicated by secondary folic-acid deficiency. On the basis of our experience with this group of patients we can conclude that though the majority of Asians with megaloblastic anaemia in Singapore suffer from nutritional folic-acid deficiency, there is yet a distinct minority who suffer from pernicious anaemia and who need specific vitamin-B_{12} therapy. Four of our six pernicious anaemia patients were Chinese, and belonged to a racial group which forms 70% of the total population of the State of Singapore. The remaining two patients were South Indian Tamils belonging to a racial group which forms 6% of the total population of the State. Another noteworthy feature was that three of the six patients—two Indians and one Chinese—had marked melanotic pigmentation of the face, particularly the circumoral area, the palms and dorsum of the hands, and the dorsum and soles of the feet. The pigmentation gradually disappeared approximately four to six weeks after the administration of vitamin B_{12}. Cases of pernicious anaemia are commonly described as presenting with pallor and a lemon-yellow tint of the skin. However, a minority may have excessive melanotic pigmentation. Sir William Osler (1916) mentions that there might be "a brownish tinge of the skin (sometimes associated with leucoderma) deep enough to suggest Addison's disease." Though Baker *et al.* (1963) described similar pigmentation in patients with nutritional vitamin-B_{12} deficiency, it is worth reiterating its occasional presence in patients suffering from pernicious anaemia also.

Summary

During a period of three and a half years six cases of pernicious anaemia in Asians were detected among routine admissions to a local medical unit in Singapore. Four were Chinese and two were Indians, and in all six the criteria for a diagnosis of pernicious anaemia were fulfilled. All made an excellent response to vitamin-B_{12} therapy.

We are grateful to Professor D. L. Mollin for carrying out the vitamin-B_{12} and folic-acid assays. We wish to thank Major G. Vasey, R.A.M.C., and Mr. John Baxter, of the Radioisotope Diagnostic Laboratory, British Military Hospital, Singapore, for carrying out the vitamin-B_{12} absorption tests. We are indebted to

Mr. V. Jayasekeran, of the Haematology Laboratory, Thomson Road General Hospital, Singapore, for carrying out most of the routine haematological investigations on our patients.

Effects of Rabies Vaccine in Man

J. C. M. SHARP,* M.B., CH.B., D.P.H.; SHEILA McDONALD,† M.D.

Brit. med. J., 1967, 3, 20–21

Few opportunities are available in the United Kingdom to study the effects of rabies vaccine in man. Immunization is restricted to those exposed to a definite risk of infection as the course is prolonged, is painful, and may be associated with complications such as peripheral neuritis, dorsolumbar myelitis, and acute ascending Landry type myelitis; major paralytic incidents develop in about 1 in 6,000 persons given treatment (Parish and Cannon, 1962).

In 1965 an opportunity arose in Edinburgh to study the effects of the Semple vaccine, a killed virus suspension of rabbit origin, which was used to immunize 20 persons who had been exposed to infection from a rabid leopard cub.

Epidemiological History

On 30 October 1965 a 3-month-old leopard arrived at Edinburgh Zoo by air from Nepal. On arrival the animal was emaciated and attempts to force-feed it failed. The animal's condition deteriorated and four days later it was transferred to the Royal (Dick) Veterinary College in Edinburgh, where it died the next day. Encephalitis was found at post-mortem examination and inclusion bodies in the brain tissue suggested the diagnosis of rabies. The animal's head was sent to the Central Veterinary Laboratory, Weybridge, Surrey, for further examination.

At the zoo it was found that four adults (A, B, C, and D) and three children (E, F, and G) had received bites, scratches, and licks from the leopard (Table I). Three adults (A, B, and C) and one child (E) who had been bitten on their hands were given a single dose of antiserum and with the others were started on a 14-day course of Semple vaccine before rabies was confirmed. One week later a further five persons (H, I, J, K, and L) admitted contact with the leopard and were also given vaccine. Four were employees of British European Airways at Edinburgh Airport, who had allowed the animal to lick their abraded hands. The fifth (L) had fed the animal at the zoo but had later left for other employment.

On 2 December the laboratory at Weybridge confirmed the diagnosis of rabies after mice inoculation tests. It was then decided to vaccinate eight other persons who had been at some risk. Four (M, N, O, and P) were zoo employees who had not previously admitted their contact with the animal. The others were a kennel maid (Q) and three veterinary surgeons (R, S, and T) at the Royal (Dick) Veterinary College, who had had their scratched hands in the animal's mouth. The four contacts (A, B, C, and E) most seriously at risk and one other (D) were given further treatment. Four (A, B, D, and E) were given six additional doses of vaccine, but C, who became unwell, received only four doses. The first four doses were given daily, beginning one week after completion of the original 14-day course; the remaining two booster doses were given to A, B, D, and E at 10-day intervals.

Three other persons had been in contact with the animal, but as they had not been bitten, scratched, or licked, no vaccine was given. In all, 20 persons were vaccinated (12 males and 8 females). Their ages ranged from 8 to 59.

The Vaccine and its Administration

The vaccine, obtained from the Lister Institute of Preventive Medicine, Elstree, Herts, was a sterile preparation of killed rabies virus in 0.5% phenolized saline containing a 4% suspension of the brains of rabbits that had died after inoculation with "fixed" rabies virus. Graded doses were given, varying from 2 to 4 ml. for the adults and from 1.5 to 2.5 ml. for the children. The daily injections were made subcutaneously into alternate sides of the anterior or lateral abdominal wall. All

vaccinated were encouraged to lead a normal life but warned to avoid excessive fatigue and alcohol during vaccination (Parish and Cannon, 1962) and for 10 days after the course.

Reactions

Six persons had their vaccine course interrupted because they felt unwell. Thirteen reported symptoms by the fourth day. A further three complained by the end of the first week and the remaining four reported symptoms by the 13th day (Table II). The earliest symptoms were increasing physical lethargy (17 cases), sleepiness during the day (16), and difficulty in wakening in the morning (10). Only L and T had no such complaints.

+ + + = Severe. + + = Moderate. + = Minimal.

Nineteen persons complained of erythema, induration, and tenderness around the injection sites. Pruritus was reported by 15 persons, including J, who had no other local symptoms. Axillary lymphadenopathy was observed in seven persons, two of whom (R and H) also developed inguinal adenitis.

Mental symptoms such as impaired concentration (14 cases) and forgetfulness (11) also occurred during the first week. Six persons reported episodes of confusion of thought, three of whom also experienced amnesia. Difficulty in getting off to sleep or nightmares were reported by six persons, one of whom had frequent nocturnal emissions.

Headaches of varying severity and frequency were experienced by 13 persons. Three persons, including two of the children, had difficulty with visual focusing. Single fainting attacks were reported by two persons during the first week. Episodes of acute nervous tension and frontal headache were experienced by C after the 18th injection. These symptoms, which recurred with diminishing frequency for six weeks, resulted in his being confined to bed at home.

Neurological symptoms developed in six persons. The most seriously affected was H, who developed acute left-sided motor and sensory disturbances, including paresis of the deltoid, triceps, and hemidiaphragm on the seventh day. This resulted in his admission to hospital, where his vaccine course was completed under corticosteroid cover. Temporary paraesthesia of the extremities was reported by I and T. H and I also complained of intention tremor when writing. Intermittent weakness of the quadriceps was reported by N, while R experienced frequent twitching in unrelated muscle groups.

Less common experiences were dryness of the mouth with marked thirst (A, B, and D), anorexia (B), frequency of micturition (A), difficulty in maintaining urinary flow (H), diarrhoea (D and O), low backache (D and N), and alopecia (C).

Discussion

Though many of the reactions experienced by the 20 vaccinated persons were minimal, some of which were reported in retrospect only, two persons (C and H) were seriously ill and absent from work for two and three months respectively. Others suffered severe discomfort.

Several persons aggravated their symptoms by failing to restrict physical exertion. However, the three children and M (aged 15) were not seriously affected despite continuing normal physical activities. It may be that susceptibility to vaccine reactions increases with age. The two persons most seriously affected were aged 59 (C) and 40 (H).

Some of the symptoms described above may have been psychological in origin, but this report does show that a high incidence of reactions can follow immunization with the Semple vaccine. Passive immunization with rabies antiserum may give better protection than active immunization, but to be of value it must be administered within 72 hours of exposure. Until more conclusive evidence is available, active immunization will continue to be part of post-exposure treatment (Hildreth, 1963). Attempts to develop vaccines less hazardous than the Semple preparation have not been entirely successful. The duck embryo vaccine was thought to be devoid of the tissue component responsible for neurological complications, but this has not been substantiated. The high-egg-passage Flury vaccine which is used for pre-exposure immunization is not recommended for post-exposure treatment (Horsfall and Tamm, 1965). Post-infection treatment of guinea-pigs has also shown that the protection given by the duck embryo or the high-egg-passage Flury vaccine is less than that given by the Semple vaccine (Veeraraghavan and Subrahmanyan, 1963).

Though quarantine arrangements are approved by the Department of Agriculture and Fisheries in Scotland, only verbal instructions are given to zoos regarding precautions to be taken with imported animals. Written instructions, however, are issued to all other registered quarantine stations. In view of the incident reported here, it is strongly recommended that similar written instructions be given to and be implemented at zoos. This report emphasizes the importance of restricting human access to animals in quarantine, thus minimizing the number of persons exposed to possible infection and subsequently to the hazards of immunization.

Summary

An outline is given of the reactions experienced by 20 persons who were immunized with Semple rabbit-brain vaccine after exposure to infection from a rabid leopard cub. Two persons were seriously ill and others suffered severe discomfort. The importance of restricting human access to animals in quarantine in order to reduce the number of persons requiring vaccination is emphasized.

We wish to thank Dr. J. L. Gilloran, Medical Officer of Health, City of Edinburgh, for permission to publish this paper; also Dr. A. Jamieson, Mr. J. Norval, veterinary inspector, and the Tropical Diseases and Infectious Diseases Unit of the Edinburgh City Hospital for their valuable assistance.

Thymectomy in Subacute Sclerosing Leucoencephalitis

O. KOLÁŘ,* M.D., C.SC.; M. OBRUČNÍK,† M.D., DR.SC.; L. BĚHOUNKOVÁ,‡ M.D., C.SC.
J. MUSIL,§ M.D.; V. PĚNIČKOVÁ,|| M.D.

Brit. med. J., 1967, **3**, 22–24

Subacute sclerosing leucoencephalitis is a well-known inflammatory affection of the central nervous system occurring predominantly during childhood and adolescence. Clinically, the initial phase of mental disturbances is followed by extrapyramidal signs associated with hyperkinesis. The E.E.G. is typical. In the cerebrospinal fluid gamma-G-globulins are raised and qualitatively altered. Subacute sclerosing leucoencephalitis is nearly always fatal, death occurring within a few months or some years after onset of the initial signs.

Sixty-nine patients with subacute sclerosing leucoencephalitis have been observed by us, six of whom are still alive. We think its incidence has increased in Czechoslovakia during the past 20 years, and we have therefore tried to find new methods of treatment. The present report deals with one patient with subacute sclerosing leucoencephalitis who was treated by thymectomy.

Case Report

Towards the end of his 13th year the patient showed a deterioration in his intellectual capacity, and his school results became unsatisfactory. There was a slow development of periodic choreiform hyperkineses of the muscles of the face and hands, particularly of the right one, together with a slight flexion of the trunk. In May 1965 he began to complain of deteriorating vision. He was no longer able to dress himself nor could he use common objects, such as a knife and fork. In September he had his first generalized epileptic fit.

On examination he could control his movements only with difficulty; he was negativistic and repeated sentences and words in a stereotyped way, and joked inappropriately. Hypertonia of the muscles and higher postural reflexes appeared, which were more marked in the right hand and foot, while there was also choreoathetosis, repeated at intervals of four to nine seconds. There was an inconstant Chaddock sign and fanning of the toes, more consistently on the right, but no patellar or ankle clonus was ever elicited. No sensory loss was found. Psychiatric findings suggested a hebephrenic syndrome arising out of leucoencephalitis. The E.E.G. picture showed periodic, high, diffuse delta waves typical of subacute sclerosing leucoencephalitis. In the cerebrospinal fluid there were 3 cells/cu. mm., predominantly lymphocytoid with reticulomonocytic elements; the total proteins were 45 mg./100 ml., the colloidal gold curve was 666543110; immunoelectrophoresis revealed a gamma-C-fraction and an increase in the anodic part of gamma-G-globulins. In the ventricular fluid 58 mg. of total protein per 100 ml. was found and the gold curve was 455543210.

The complement-fixation reaction (Běhounková, Kadlec, and Kolář, 1966), with 0.3 ml. of the patient's C.S.F. and a standardized antigen prepared from the brain of a patient with subacute sclerosing leucoencephalitis, was strongly positive (+ + +). The antigen used in the complement-fixation test was tested on 26 patients with subacute sclerosing leucoencephalitis, from 0.1 to 0.5 ml. of spinal fluid being used. With one exception the complement-fixation reaction in cerebrospinal fluid was positive at various degrees (+ to + + +) in these patients. The antigen as described here is not absolutely specific for subacute sclerosing leucoencephalitis, as it reacted to the spinal fluid of five patients out of a total of 288. These five all had inflammatory diseases of the brain.

The complement-fixation reaction is graded according to the amount of complement used in comparison with a control; + indicates use of 1 to 2 units, + + corresponds to 2 to 3 units, and if more than 3 units of complement are used the reaction is graded + + +. The antigen did not react with the serum of the control subjects, but with the sera of two out of 26 patients with subacute sclerosing leucoencephalitis, and then only with an intensity of +.

Radiological investigation showed enlargement of the spleen, liver, and thymus (Fig. 1). In the serum the acid-phosphatase concentration was 7.7 units/100 ml., and the alkaline-phosphatase concentration 20.0 units/100 ml. The levels of fibrinogen, plasmin, plasmogen, and antiplasmin were within physiological limits. Brain biopsy showed a perivascular mononuclear infiltration, particularly around the veins, and a pericapillar increase in acid mucopolysaccharides (stained with alcian blue). Inclusion bodies were not found. Immunoelectrophoresis of brain tissue extract demonstrated as increase in gamma-G-globulins. By means of the transbronchial diagnostic pneumomediastinum with oxygen (Pěgřim, Ríha, and Simeček, 1957), hyperplasia of the thymus was shown. Attempts

§ Senior Consultant in Chest Diseases.

|| Senior Consultant in Neurology.

From the Clinic of Neurology, Department of Histology and Embryology, Department of Microbiology, and Clinic of Lung Diseases, Palacký University, Olomouc, Czechoslovakia.

at virological isolation from the biopsied brain material and from the C.S.F. were persistently negative.

Despite corticosteroid treatment the symptoms steadily got worse. Because enlargement of the thymus had been found thymectomy was performed in November 1965; the thymus weighed 19.8 g. Histologically the thymus showed disappearance of the border between the cortex and the medulla of the thymus, hyperplasia of the reticular cells (Fig. 2), and numerous enlarged cystically altered Hassall's corpuscles (Fig. 3). Histochemically the substance in Hassall's corpuscles showed a positive reaction after staining by periodic-acid–Schiff. Alcian blue staining reaction was also positive.

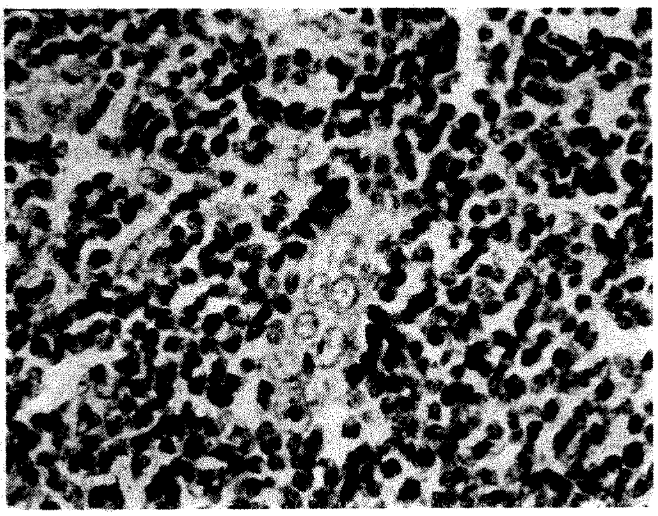

FIG. 2.—Collection of hyperplastic reticular cells. (H. and E. ×126.)

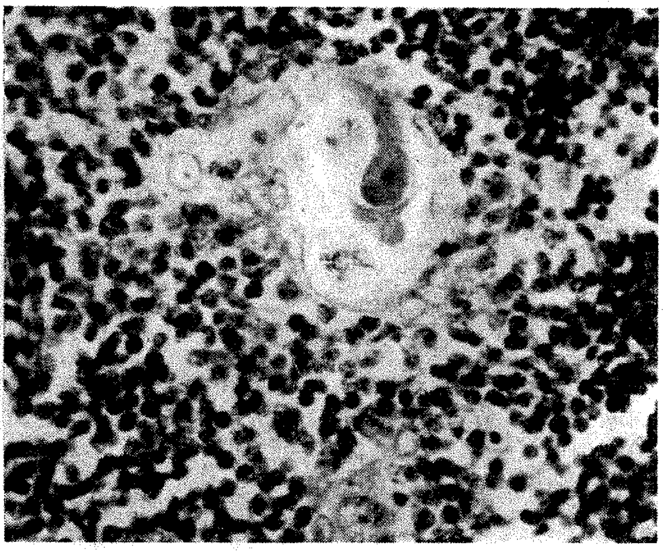

FIG. 3.—Above, Hassall's corpuscle with atypical arrangement of reticular cells. (H. and E. ×106.) Below, Cystically changed Hassall's corpuscle. (H. and E. ×63.)

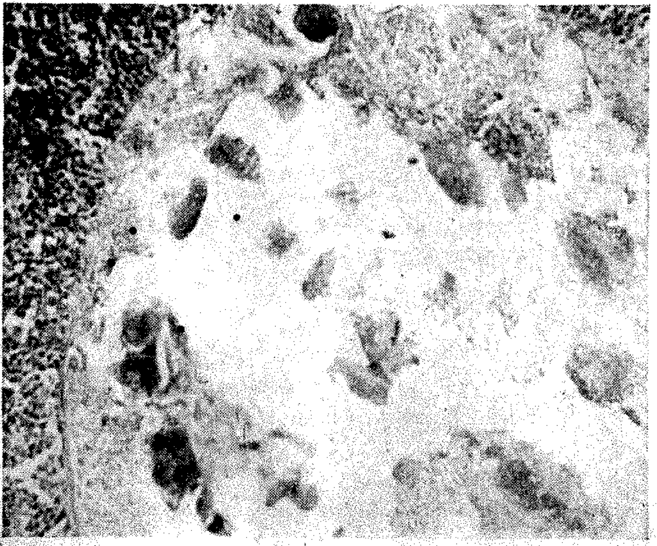


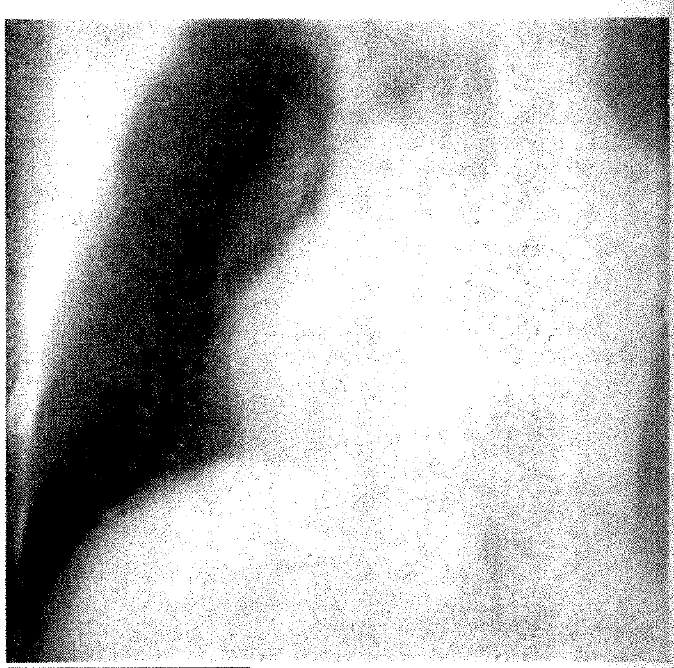
Within two weeks of thymectomy the patient's hebephrenic syndrome had improved, and this improvement has been maintained, together with a diminution in the extrapyramidal signs. After four months a repeat examination of the C.S.F. was carried out. This showed a concentration of 40 mg./100 ml. (with 22% of gamma-globulin) and a gold curve of 223321000. Autoantibodies were still present in the C.S.F. The E.E.G. picture still showed typical pseudorhythmic R-complexes. Agar-gel electrophoresis of the serum showed two abnormal fractions of gamma-G-globulins of slow electrophoretic mobility. The acid-phosphatase concentration fell to 5.9 units/100 ml.

The duration of subacute sclerosing leucoencephalitis from the onset of the first clinical signs of the disease has so far been more than two and a half years.

Control Examination.—Seventeen months after thymectomy the patient is free of seizures and hyperkinesias. Pyramidal signs are lacking. This improvement of the neurologic syndrome is unfortunately not matched by a similar alleviation of the psychologic impairment. The patient is imbecile, though he can take care of his needs, and recognizes relatives and physicians. He is still on prednisone and antiepileptics.

Discussion

Enlargement of the thymus was also seen in three other patients out of nine with subacute sclerosing leucoencephalitis examined by pneumomediastinum produced by the transbronchial route with oxygen. Fig. 4 shows thymic hyperplasia in a 15-year-old boy with subacute sclerosing leucoencephalitis. In the course of prolonged treatment with corticosteroids,



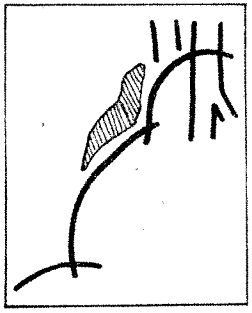


FIG. 4.—Thymus hyperplasia in a 15-year-old boy with subacute sclerosing leucoencephalitis

the clinical picture showed apparent stabilization of the abnormal neurological signs in these patients, and the 15-year-old boy has so far lived for more than four years since the onset of the illness.

Subacute sclerosing leucoencephalitis is accompanied by an increase and a qualitative change in the cerebrospinal fluid gamma-G-globulins (Kolář, 1966a) and by appearance of autoantibodies against the brain-tissue antigen in the C.S.F. of subacute sclerosing leucoencephalitis patients (Běhounková *et al.*, 1966). The symptoms and laboratory manifestations of subacute sclerosing leucoencephalitis may have a remittent course. Other manifestations of the disease include splenomegaly, hepatomegaly, and pathological changes, mainly in the cathodic part of the serum gamma-G-globulins (Kolář, 1966c ; Kolář, Obručník, Fárková, Dvořák, and Musil, 1967).

Examination of biopsy or necropsy brain tissue from patients with subacute sclerosing leucoencephalitis has shown mainly perivenous collection of mononuclear cells which probably contain glycolipoprotein complexes, since these fluoresce when examined by ultraviolet light. Moreover, the presence of abnormal gamma-G-globulins in these specimens from patients with subacute sclerosing leucoencephalitis has also been shown (Kolář, Dencker, Obručník, Černá, and Skatula, 1966).

The perivascular mononuclear infiltrates in the brain, persisting for months to years, the increase and the qualitative changes of gamma-G-globulins in brain tissue, the participation of the extraneural reticuloendothelial system in the development of subacute sclerosing leucoencephalitis, together with the presence of antibodies against a brain-tissue extract used as antigen in the cerebrospinal fluid, all suggest a neuroimmunopathological basis for this disease. This process seems to be not completely analogous with the immunological events leading to experimental allergic encephalomyelitis.

Involvement of the thymus in the development of autoimmune processes, particularly those in which delayed hypersensitivity is concerned, is now generally accepted (Good, Finstad, Peterson, Kellum, and Surtherland, 1965 ; Loghem, 1965). Nevertheless, thymectomy, especially in older subjects, does not prevent the appearance of autoantibodies (Kerr, Duran, Thomas, and Wright, 1965). So far the therapeutic effects of thymectomy in myasthenia gravis have not necessarily been found to be beneficial. Some improvement after thymectomy was described in a patient with systemic lupus erythematosus (Mackay, Goldstein, and McConchie, 1963), but this could be attributed to prednisolone therapy.

The improvement in the neuropsychiatric symptoms in our patient with subacute sclerosing leucoencephalitis is noteworthy, though it can hardly be ascribed to the corticosteroid therapy, which was given in small doses. Nevertheless, a spontaneous remission of the subacute sclerosing leucoencephalitis, which was accompanied also by a fall in the cerebrospinal fluid gamma-G-globulins, cannot be excluded in this case.

Thymic hyperplasia in patients with subacute sclerosing leucoencephalitis suggests that the "central" lymphoid tissue may play a part in the development of the disease. Possibly the thymus influences the development of subacute sclerosing leucoencephalitis unfavourably by supporting the autoimmune histotoxic process, but the right moment to recommend thymectomy in patients with subacute sclerosing leucoencephalitis will be determined only by careful study of further cases of the disease.

Summary

Enlargement of the thymus may be found in some patients in the course of subacute sclerosing leucoencephalitis. We describe a case of subacute sclerosing leucoencephalitis treated by thymectomy in which considerable improvement resulted.

We thank Professor V. Rapant, M.D., Dr.Sc., head of I Clinic of Surgery, Palacký University, Olomouc, for his co-operation.

Renal Colic

JAMES A. RHIND,* F.R.C.S.

Brit. med. J., 1967, **3**, 24–25

Since 1958 an "immediate" intravenous pyelogram (I.V.P.), taken while the pain is actually present, has been used in the routine investigation of cases of suspected renal colic admitted to the Pontefract General Infirmary. This is a busy hospital, and it has often been necessary for the consultants to delegate to junior staff the responsibility for the initial diagnosis and supervision of the *x*-ray films, which were often taken by junior radiographers during the evening and the night. The details of the *x*-ray examination have varied, but in general we have taken a control film, and films 10 and 30 minutes after the injection of the intravenous medium. Further films were taken until the ureter was outlined ; this may not happen until as long as 24 hours, but the rate of appearance of the nephrogram can be a guide to the timing of the later films.

While a typical attack of renal colic can be recognized confidently, in the atypical attack an immediate intravenous pyelogram showing delayed excretion, a nephrogram, and slow filling of the kidney drainage system compared with the normal side provides impressive confirmation of the obstruction to the kidney and permits the use of strong analgesics. The further management of the case depends on the demonstration of the cause of the obstruction.

Results

The results in the 146 cases in which immediate I.V.P. was carried out were: stones in 84 cases, abnormal *x*-ray films in 27, normal *x*-ray films in 31, and other diseases in 4.

---

* Consultant Surgeon, Pontefract and Castleford Hospital Group, Pontefract, Yorkshire.

Stones

We were impressed by the number of stones revealed by this routine. In some cases several films were required before an apparent phlebolith in the pelvis was indicated as a calculus by coincidence with the termination of a dilated ureter, the diagnosis being confirmed by the disappearance of the shadow after passage of a stone. In other cases a large shadow was quickly proved to be a ureteric calculus. During the same period ureteric calculi were discovered in outpatients referred after an attack of renal colic or with other urinary symptoms, and the management of these cases (called "late I.V.P.") is compared with the cases of immediate I.V.P. in the accompanying Table. A further group of cases we have called "delayed I.V.P." These patients were admitted to hospital with renal colic, but an immediate I.V.P. was not taken because either the pain had ceased or pressure of work in the *x*-ray department prohibited the examination. In these cases the I.V.P. was usually taken about four to seven days after admission.

Fate of Calculi in the Ureter

	Size of *X*-ray Shadow of Stone	I.V.P.					
		Immediate		Delayed		Late	
		Passed	Op.	Passed	Op.	Passed	Op.
Abdominal ureter	3 mm. or less	6	1				1
	4 ,, ,, more	2	6		1		5
	Not known	3	2		1		2
	Total ..	11	9	0	2	0	8
Pelvic ureter	2 mm. ..	32		2		3	
	3–5 mm.	21		4		8	1
	6 mm. or more	2	3	1	1		3
	Not known	6		4		7	3
	Total ..	61	3	11	1	18	7

It is apparent that most of the stones revealed by the immediate I.V.P. are small, are at the lower end of the ureter, and pass spontaneously. Operative intervention was more common when the immediate I.V.P. showed a stone in the abdominal ureter; ureterolithotomy in this area is easy and safe, and failure of the stone to move for a few days was usually taken as an indication for operation. How many of these stones would have passed is uncertain, but the occasional stone which moved slowly was a source of anxiety for weeks. The late I.V.P. series showed a much smaller proportion of small stones and more of these cases were treated by operation; in four cases the kidney was so damaged that nephrectomy was performed. It would seem that the agonizing pain of renal colic requiring admission to hospital implies a healthy kidney and the recent movement of a small stone to the ureter, from which it will probably soon pass. The kidney that has been damaged by the growth of a larger calculus in the ureter can manage only a feeble protest which brings the patient to the outpatient clinic.

Abnormal X-ray Films

In 27 cases the immediate I.V.P. showed some or all of the signs of obstruction—namely, delayed excretion, nephrogram, hydronephrosis, and delayed emptying of the ureter—but without the shadow of a stone being visible. In five of these cases the examination was not continued long enough to demonstrate the whole ureter. In two the patient failed to empty the bladder, and the lower end of the ureter was obscured. In only one case did we find that faecal and gas shadows prevented adequate examination of the ureter. Thus in 19 there was evidence of obstruction without stones. Two of these patients subsequently passed stones. In the stone series occasionally a ureteric shadow disappeared during the course of the examination, with passage of a calculus, but the signs of obstruction persisted for a little time. We are prepared to accept the thesis that in the absence of other disease renal colic is always due to the presence of a stone.

Normal X-ray Films

If the pain of renal colic is due to a rise in pressure in the ureter and kidney pelvis, it is difficult to see how this can occur without radiological abnormality. In 31 cases the immediate I.V.P. was normal though the diagnosis of renal colic seemed well established by a typical history, the presence of red cells on microscopy of the urine, redness and swelling of the ureteric orifice on cystoscopy, or the passage of a calculus. In some cases an overzealous junior resident carried out an immediate I.V.P. even though the patient's pain had disappeared on admission to hospital. In other cases the *x*-ray department could not arrange an I.V.P. for some hours and the pain disappeared during the period of waiting. Strong analgesics are required for the relief of the pain of renal colic and it may be impossible to say whether the disappearance of the pain is due to the analgesic or the actual relief of the obstruction. Each of these explanations probably applied in some cases, but unfortunately our records are not detailed enough to be sure that they explain all the normal I.V.P.s. Nevertheless, we are left with a strong feeling that a normal I.V.P. taken while the patient has continuing pain makes the diagnosis of renal colic unlikely.

Other Diseases

This series included one case of renal tumour with haematuria, pyelonephritis, massive hydronephrosis, and renal arterial embolism.

Discussion

An immediate I.V.P. for all cases of renal colic imposes a heavy strain on an *x*-ray department, but the value of the examination justifies the procedure. A normal I.V.P. requires serious reconsideration of the diagnosis, while the proof of renal obstruction reassures the doctor in continuing analgesia. The demonstration of a small stone (4 mm. or less) at the lower end of the ureter—and this will be the case in a great number—allows the patient to be sent home if the general practitioner will provide suitable analgesia. It is important that these patients are seen in the outpatient clinic until the stone has been passed. A larger stone (4 mm. in the upper ureter or 6 mm. in the pelvic ureter) may need early operation unless it is moving quickly. Perhaps the general adoption of this policy might prevent the tragedy of the late case which requires removal of a destroyed kidney rather than ureterolithotomy.

Summary

Investigation of 146 cases of renal colic by immediate intravenous pyelography showed that most cases are due to calculi, and that the few that need operation can be selected at an early stage.

Asymmetrical Rheumatoid Arthritis after Poliomyelitis[*]

E. N. GLICK,[†] M.B., M.R.C.P., D.PHYS.MED.

Brit. med. J., 1967, 3, 26–29

An outstanding feature of rheumatoid arthritis is its tendency to be bilateral and symmetrical. This is one of the generally accepted diagnostic criteria, as suggested by the American Rheumatism Association (Ropes *et al.*, 1958). Jacqueline (1953) and Thompson and Bywaters (1962) have described unilateral rheumatoid arthritis, sparing the paralysed side, after hemiplegia. The only report of similar sparing of a paralysed limb after lower motor neurone paralysis is that by Kamermann (1966), though Heberden's nodes formation limited to the non-paralysed hand has been described after lower motor neurone paralysis by McEwen (1940), Hench (1940), and Stecher and Karnosh (1947) and after hemiplegia by Coste and Forestier (1935), Forestier (1935), and Winter (1952).

This paper records 12 cases of rheumatoid arthritis developing in patients previously paralysed by poliomyelitis, in whom the paralysed limbs have been spared totally or partially by the arthritic process.

In addition, a woman of 84 was seen who started with low-grade rheumatoid arthritis at the age of 57. She had had a virtually complete right hemiplegia since encephalitis at the age of 2, and the arthritis was almost entirely confined to the normal left arm and leg.

During the course of this investigation several patients with osteoarthritis after poliomyelitis were also seen. On superficial analysis they would appear to fit in with the findings of Glyn *et al.* (1966) that osteoarthritis predominantly affects the non-paralysed limbs.

Case Material

Cases 1 and 2 were seen in clinics at the London Hospital. A search through the hospital records brought to light Cases 3 and 4; the former patient had died and the latter had removed and could not be found. Cases 5 and 6 were contacted through the co-operation of the British Polio Fellowship, who published a notice in their *Bulletin* asking for anyone with arthritis and polio who was willing to volunteer details. These were the only two with rheumatoid arthritis of those who replied, and they were seen by me.

These six cases formed the material for a communication to the Heberden Society in May 1966. Subsequently, several physicians offered details of similar cases known to them; these are Cases 7–12. I did not examine these patients but have seen the *x*-ray pictures. I know of no other cases of rheumatoid arthritis occurring after poliomyelitis. All but one patient (Case 10) were women.

Dr. A. J. Popert (Droitwich) sent details of a patient with atypical polyarthritis who had polio at the age of 5, resulting in a weak left leg and flail left foot. At the age of 24, arthritis began in the left knee, spread rapidly to the right knee, and then became generalized. She is anodular and seronegative. There are marked sacroiliac changes. Now, at the age of 32,

Summary of Salient Features of 12 Cases

Case No.	Age	Extent of Paralysis and Degree (0 – + + +)	Arthritis		Serology	Subcutaneous Nodules	*X*-ray Findings
			Duration (Years)	Distribution			
1	67	Left leg + + +	5	Right hip and knee. Both hands and elbows	–	0	Symmetrical erosions in hands. Gross changes in right hip and knee, but none in left hip and knee
2	46	Right leg + +	12	Generalized but mild. Symmetrical in upper limbs. Left knee definitely the most affected joint with recurrent effusions	+ +	0	Erosions of hands and wrists, worse on right. No gross changes in lower limbs
3	61	Left leg +	22	Generalized and mainly symmetrical, but right knee seems to have been much more troublesome than the left	+	Both elbows	Not available
4	25	Right leg + +	2	Left knee only. (Synovial biopsy typical of R.A.)	–	0	Osteoporosis of left knee
5	38	Trunk +. Left leg + + +. Right hip +	2	Symmetrical involvement of elbows, wrists, and hands. Gross changes in right knee and minor involvement of right ankle	–	0	Erosions of both carpi. Gross destruction of right knee
6	45	Right leg + +. Left leg +	11	Fairly symmetrical bilateral involvement of upper limbs. Both knees troublesome. Left ankle and foot worse than right	–	0	Erosive changes in hands. (No recent bilateral films of lower limbs)
7	76	Right arm + +. Right leg +	20	Virtually unilateral, involving only the unparalysed left arm and leg	+	Left elbow	Erosive changes in left hand and foot
8	53	Left leg + + +	14	Generalized. Symmetrical in upper limbs. Unilateral in lower limbs—right knee and ankle only	–	0	Joint space narrow in both knees, but very much more so on right
9	57	Left arm + + +. Right leg + +	31	Generalized. Changes in right hand and wrist more marked than in left. Left knee and foot more severely affected than on right	+ +	Right elbow and left leg	Erosive changes more marked in right arm and fingers. Gross cartilage loss in left knee but not in right. Subluxation of metatarsophalangeal joints of feet, more marked on left
10	45	Right arm + +	7	Bilateral involvement but less marked in right elbow, wrist, and hand. (Psoriasis of skin but no features typical of psoriatic arthropathy)	Not done	0	Slight erosive changes in right wrist but not in fingers. Marked erosions of left hand and wrist. Erosive changes in feet, more marked on right
11	62	Right arm + + +. Right leg + +	4	Pains in left shoulder, hand, ankle, and foot. Left index metacarpophalangeal joint swollen (i.e., not definite R.A.)	–	0	Joint narrowing limited to metacarpophalangeal joint of left index
12	73	Left shoulder + + +	2	Both hands, wrists, and ankles. Right shoulder	+ +	0	Destructive changes in both wrists and several finger joints

---

[*] I gratefully acknowledge the co-operation of the following physicians: Dr. W. S. Tegner (London), Dr. R. M. Mason (London), and Dr. N. Bennett-Jones (Whiston), who allowed me to examine and report on patients under their care; Dr. Charlotte Feldman (London), Dr. D. N. Golding (Harlow), Dr. H. Jacobs (London), Dr. M. R. Jeffrey (Harrogate), and Dr. M. Wilkinson (Bridge of Earn), who sent details of their patients. I wish to thank the British Polio Fellowship for their co-operation.

[†] Consultant in Physical Medicine, Metropolitan Hospital, London E.8.

there are few changes in the upper limbs or left leg, but the disease is still active in her neck, right knee, and right ankle.

Findings

The Table summarizes the salient features of each case. It can be seen that the greater the severity of the paralysis the more pronounced the sparing of the joints of that limb. Thus very little arthritis was discovered in flail limbs. In fact, it seemed that it was the joints normally controlled by the paralysed muscles that escaped the arthritis (Figs. 1–4). There was good correlation between the clinical and radiological findings.

Subcutaneous nodules were present in three cases (Nos. 3, 7, and 9). In Cases 7 and 9 the nodules occurred on the non-paralysed limbs but not on the opposite, paralysed, side. This was particularly striking in Case 9.

Discussion

These findings illustrate that joints controlled by paralysed muscles show less involvement and destruction when rheumatoid arthritis develops. This is in marked contrast to the denervated neuropathic joint in which hypertrophic and destructive changes are very severe.

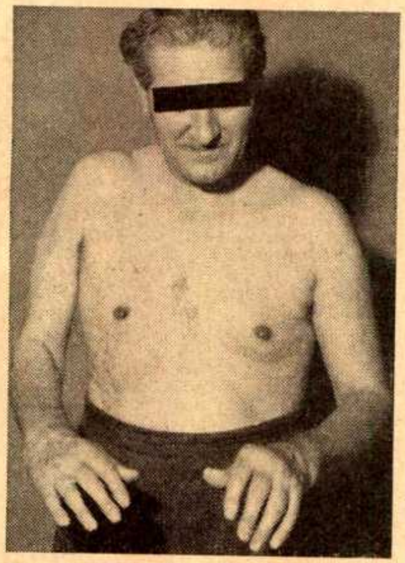

FIG. 1.—Case 10. Wasting of right shoulder muscles. More severe changes in left metacarpophalangeal and proximal interphalangeal joints with ulnar deviation.

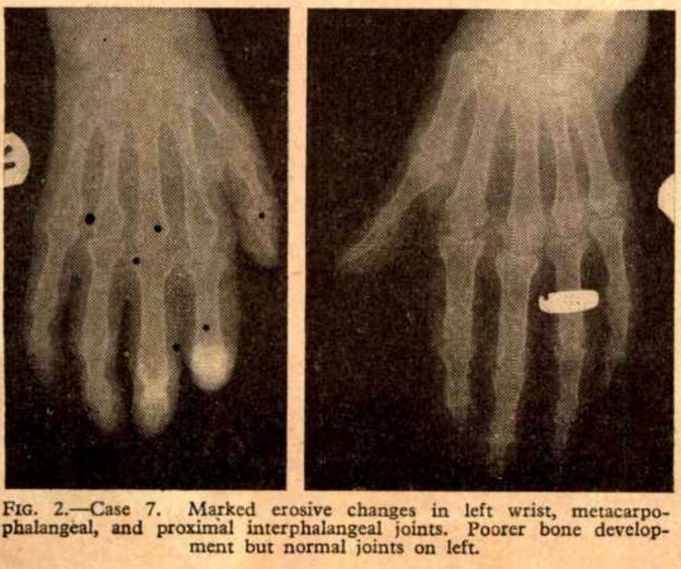

FIG. 2.—Case 7. Marked erosive changes in left wrist, metacarpophalangeal, and proximal interphalangeal joints. Poorer bone development but normal joints on left.

Of particular interest was the observation that subcutaneous nodules did not appear on the paralysed limbs. In their case in which an arteriogram was taken, Thompson and Bywaters (1962) found abnormalities on both sides, but these were more intense on the non-paralysed side. It would be of interest to have had similar investigations in this series, but in those patients under my clinical supervision this procedure did not seem worth while.

In their consideration of the protective effect of the hemiplegia Thompson and Bywaters (1962) came to the conclusion that the most reasonable explanation for the immunity of the paralysed side to the development of rheumatoid arthritis was the relative lack of use and function. They quoted some studies of vascular responses which were the same in the hemiplegic and non-hemiplegic limbs. Kamermann (1966) also regarded the protective effect as being due to comparative disuse rather than to the neurological lesion.

Castillo *et al.* (1965) have shown that the development of cystic erosions in rheumatoid arthritis is related to the degree of physical activity. Van Dam (1964) found no significant difference between the right and left hands in rheumatoid arthritis with regard to cartilage thinning, but erosions and cysts were more frequent on the right. In a review of 300 consecutive rheumatoid patients Glick (1966) attempted a correlation between right- or left-handedness and the severity of the disease in the two wrist joints and found just significantly more severe arthritis in the wrist of the dominant limb. In patients whose work was classified as heavy, and where marked asymmetry might have been expected if

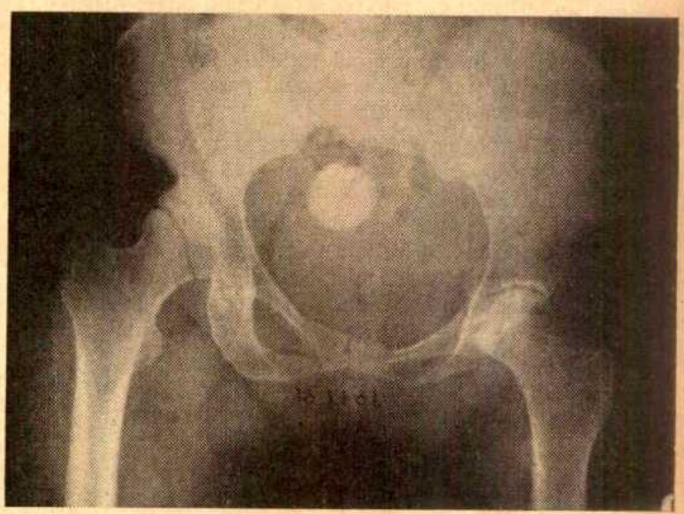

FIG. 3.—Case 1. Gross destruction of right hip joint. Decreased bone development on left, but normal joint.

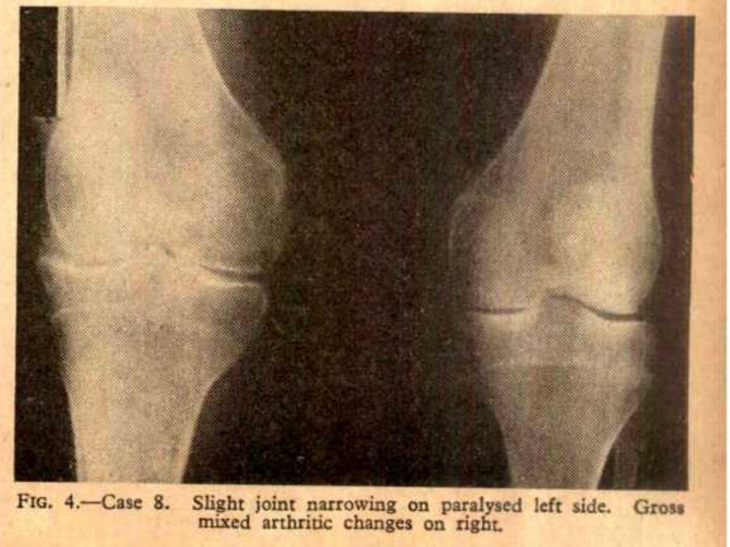

FIG. 4.—Case 8. Slight joint narrowing on paralysed left side. Gross mixed arthritic changes on right.

mechanical factors were dominant, the symmetry of the disease in many of the patients was perhaps more striking than the difference between right and left. Nevertheless, the more active limbs did seem to develop the more severe arthritic changes, and the wrist involvement did appear to begin at an earlier stage. Asymmetry was noted to be more common in seronegative cases. In the present series both seronegative and seropositive cases showed asymmetry.

The experiments of Courtwright and Kuzell (1965) are very pertinent. In 20 out of 31 rats with adjuvant polyarthritis, prior section of one sciatic nerve appeared to delay the onset and diminish the severity of the arthritis in the operated limb. Similar but less marked sparing of joints resulted from prior fracturing of the femur. These two workers attributed their results to an interruption of the normal neurological control of the limb concerned rather than to mechanical factors, but the findings of this series, and their results, also correlate with different experimental work.

Dumonde and Glynn (1962), after rendering rabbits hypersensitive to their own fibrin, were able to produce an arthritis with histology similar to rheumatoid arthritis by intra-articular injection of fibrin.

Norton and Ziff (1966) injected colloidal gold particles into a joint. At synovectomy, about an hour later, these were found deep in the synovial membrane. They consider that the joint space is in continuity with the synovial extracellular space and regard the gold particles as having been mechanically propelled into their deep situation.

If, therefore, fibrin or some other immunizing agent—perhaps a globulin complex present in the joint space—is forced into the synovium by exercise or joint movements, it might be expected that in rheumatoid arthritis joint usage would increase the severity of the disease and paralysis would minimize the inflammatory process.

The actual mechanical factor involved may be the intra-articular pressure. Dixon and Grant (1964) have shown the high pressure reached when a joint is used actively, and though this work has not been repeated on joints of paralysed limbs it is reasonable to assume that, whatever stresses occur in such joints, the intra-articular pressure does not reach the levels produced in normal limbs. It is conceivable that capsular and ligamentous stresses might even be higher in a paralysed weight-bearing limb.

Glyn *et al.* (1966) have studied the incidence of osteoarthritis in people with limb paralysis occurring after poliomyelitis. They found a positive correlation between the severity of degenerative joint changes and the power of the muscles controlling the joint. The flail limbs were relatively free from arthritis. However, it is not clear how much can be inferred between the two different types of arthritis.

What does seem clear is that after muscle paralysis the associated joints show less destructive changes of both degenerative and inflammatory arthritis than joints in the non-paralysed limbs.

The problem arises of how far these findings should influence decisions regarding rest and exercise in the management of arthritis.

Summary

Details are given of 12 cases of rheumatoid arthritis occurring in people previously paralysed by poliomyelitis. Joints controlled by the paralysed muscles were less affected than those in the contralateral non-paralysed limb. This sparing effect was most marked in completely flail limbs.

Subcutaneous nodules showed similar asymmetrical distribution in two patients.

It is suggested that decreased intra-articular pressure might be an important factor in this apparently mechanical effect.

Adverse Reactions from the Illicit Use of Lysergide

THOMAS H. BEWLEY,* M.D., F.R.C.P.I., D.P.M.

Brit. med. J., 1967, 3, 28–30

Lysergide (lysergic acid diethylamide ; L.S.D.) is a drug with marked effects on the mind. Illegal use of the drug in the United States has led to reports of untoward and adverse reactions (Cohen and Ditman, 1962, 1963 ; Ludwig and Levine, 1965 ; Frosch *et al.*, 1965). Severe abnormal reactions have also occurred in the United Kingdom when the drug has been obtained illicitly and taken without medical supervision, and some are reported here.

Case 1

A youth aged 19 was educated at a grammar school but failed G.C.E., and after leaving school at the age of 16 never worked. He then lived a vagrant existence and at different times took marijuana, oral amphetamines, intravenous heroin and cocaine, and methylamphetamine hydrochloride (Methedrine) intramuscularly. He had always obtained drugs illegally. When he first took L.S.D. he had a short-lived paranoid psychotic reaction.

"I had a bad trip the first time I took it. I thought I was in a different place to where I was. I was very frightened ; I thought people were coming after me. All these red people were coming after me for some reason. I was very scared and ran out of the room. I thought they would get me. I did not know if they were the devil's people or something. I was running about the streets scared. I don't know what happened for about four hours ; I was very frightened and running about the streets."

---

* Consultant Psychiatrist, Tooting Bec Hospital, London S.W.17.

Despite the unpleasantness of this first experience he continued to experiment with L.S.D., but did not have a similar reaction on subsequent occasions. "I never had a bad trip since then. I use it to expand my mind. I'm not against it now. I get a really wonderful experience. I use it for relaxation with music. I underestimated it the first time I took it. It took me unawares."

His current problem is physical dependence on heroin.

Case 2

A man aged 24 had a normal upbringing and education at a secondary modern school until he was 15. Then he had periods in an approved school, Borstal, and two years' imprisonment for receiving. He had taken dexamphetamine since the age of 16 and also marijuana, heroin, and cocaine. He had a cocaine psychosis with hallucinations on one occasion. He took L.S.D. once and found that he became acutely depressed and suicidal. "I felt like jumping into a pond. I had a crazy urge to." He found the experience sufficiently frightening and unpleasant to have no desire to repeat it. He had a history of depressive reactions and he slashed his wrists on one occasion in hospital, after attending the funeral of his best friend, who had committed suicide.

Case 3

A man aged 21 had a normal childhood and had done well at grammar school until he was 17, when he left after taking O levels. He then did hotel and catering training for two years and obtained a job as assistant manager of an off-licence. He was described as quiet and studious up to the age of 19. He had his own car and saved money. He started taking amphetamines at 18, and this was succeeded by experimentation with all forms of drugs. He took heroin, cannabis, and "sleeping tablets" irregularly. He tried L.S.D. once and found the effects pleasant at the time. "At first it was a vague dream. I was semi-floating. There's nothing you can't do. You throw your problems aside, think you are God." However, he had severe panic attacks later. "The after-effects were too terrifying. I would not want to repeat it. I was violently sick for a few days, my head was spinning, and I could hardly stand. I was in a deep depression and thought someone was watching me all the time. I would wake in a cold sweat, find myself lying in bed paralysed. Once you move your arm you are all right, you sit up after 20 minutes. It's frightening, you wake up and don't know if you are awake or not." He had no desire to take L.S.D. again. He had become heavily dependent on alcohol and was drinking a bottle of brandy a day, mixing it with Pernod. He had been incapable of working for two months and had spent all his savings and sold his car.

Case 4

A man aged 21 had had a very disturbed childhood and upbringing. His parents were divorced and remarried, and he was brought up by various relatives and in foster-homes. He had nocturnal enuresis until the age of 15. He was in the Merchant Navy for three years (aged 16–19). After this he had not worked. He lived with a prostitute, sold hashish, and touted for blue films in the West End of London. He was currently on probation for living on immoral earnings. He attended a V.D. clinic regularly, having had gonorrhoea several times according to his own account. He had taken amphetamines and marijuana since the age of 18, and had once jumped in front of a taxi while under the influence of amphetamines. He started taking L.S.D. and took it three times in a week. He found it produced pleasant reactions at first but later unpleasant ones, and he stopped taking it.

"It was great when it first happened, but after a while I began to get the horrors. It frightened me and I started to fight under it. Once when on L.S.D. I used violence. Two of us had taken L.S.D., me and this girl. There were two other couples, one couple I knew well, the other I did not. I thought this bloke was trying to get off with this girl I was taking a trip with. We were talking, laughing, drinking. In the hall there were me and this girl and the other fellow. He said, 'Go away please.' I went mad and started to fight him, but I cooled down quickly. I said, 'Go away for a minute.' I was frightened of him, so afterwards I apologized. I did not know how to apologize enough."

After this he stopped taking L.S.D., but continued to smoke marijuana. He found that although he had never had any unpleasant effects from smoking cannabis before he used L.S.D., when he smoked it again, after his experimentation, he began to get recurrent short-lived psychoses. "I used to smoke hashish till I could not think. I'd smoke myself silly with some friends. If I smoked with them I'd smoke an awful lot. Now, more recently, I've realized it was since taking L.S.D. I was getting more horrors. I keep getting double meanings. I was really terrified the night before last, I was just smoking hash at the time, I could see the effects like L.S.D. I thought they were wanting to kill me. I was sitting looking at myself in a mirror. They were talking about vans. I thought it was all directed at me, it was driving me nuts. I thought people were going to kill me. It was worse than after I had the L.S.D."

He found these reactions sufficiently alarming to wish to try to give up all use of drugs.

Case 5

A man aged 20 died from severe laceration of the brain associated with a fracture of the left parietal region caused by falling from a fourth-storey window on to a brick wall. This appeared to have followed his first experimentation with L.S.D.

He was a musician living in furnished rooms and had no past history of mental illness or instability. He had previously smoked marijuana and belonged to a group of people who used drugs and were interested in them. He was anxious to try the effects of L.S.D., and arranged to do this with two friends, one of whom had taken the drug before and who possessed some. On the day that this was arranged both these friends apparently changed their minds and did not go round to his room. That evening he was seen to climb out of the window of his attic room, having first broken the glass; he stumbled, slid down the roof, and fell to his death. The door of his room was found to be locked and barricaded on the inside with a chair against the door. The room was in complete disorder, with clothing, bedding, and furniture strewn all over the room. No one else was present. The gas-stove and the electric-light fittings were broken. All the windows in the room were broken, including the one he had got out of.

At necropsy it was not possible to confirm the presence of L.S.D., though it appears likely that it had been taken. There was no evidence at necropsy that he had taken any other drugs, such as amphetamines.

Case 6

A man aged 20 died from multiple injuries (fractured skull, fractured pelvis, fractured right tibia and fibula) caused by jumping or falling 60–70 ft. (18–21 m.) from a church roof. He was a bricklayer's labourer and had no history of serious illness or accident, nor was there any history that he had previously taken L.S.D. On the Saturday night before his death he apparently went to a club in Soho with a girl, who could not subsequently be traced. On Sunday morning at 10 o'clock he was found lying naked in the forecourt of a church in Highgate. His clothes had been left in a neat pile on the roof. Necropsy showed that he had died from multiple severe injuries, and analysis of specimens of blood (peripheral), liver blood, heart blood, bile, and stomach contents gave the following results (Dr. Ann E. Robinson): "(1) Routine screening tests for alcohol and 5,5-disubstituted barbituric acid derivatives in the peripheral blood sample were negative. The stomach contents also gave negative results from these substances. (2) The specimens of bile (6 ml.) and the remaining peripheral blood (11 ml.) were examined for the presence of lysergic acid diethylamide (L.S.D. 25). A substance was detected in both of these samples which had properties consistent with those of L.S.D. 25, though unequivocal proof of identity of the recovered substance was lacking."

It seems likely that this man had taken L.S.D. at some stage after his visit to the club and had then climbed to the top of a church, taken all his clothes off, put them in a neat pile, and jumped or fell to his death. It is possible that he had a psychotic reaction or he may have had such changes in mood (euphoria or elation) that he believed he could float safely down.

Discussion

There has been an increase recently in the use of L.S.D. in this country on a casual basis and not under medical supervision. Use in this way as a "mind-expanding" drug has been extensively discussed in the press and on television, and has been advocated in non-medical journals. After a similar interest in the non-medical uses of the drug and extensive self-medication by fringe groups in New York there was a sudden upsurge of admissions to Bellevue Hospital with acute reactions from its use (Frosch *et al*., 1965). These fell into three groups: (1) acute panic reactions; (2) recurrence of symptoms while abstaining from the drug, which was more likely to occur after multiple ingestion; and (3) prolonged psychosis.

Cases 1, 2, and 5 reported here appeared to be acute panic reactions, and Cases 3 and 4 a recurrence of symptoms in a period of abstinence. Case 4 also showed signs of a prolonged psychosis. Case 6 may have been due to disordered judgement or a psychotic reaction. Prolonged adverse reactions, including chronic hallucinatory states, also occur (Rosenthal, 1964). Owing to the fashion of using sugar cubes as a vehicle for black market L.S.D. it can also be taken accidentally—for example, by children—and three such cases have been reported. One of these sustained a dissociative state, accompanied by anxiety and visual illusions, that lasted for several weeks (Cohen, 1966). Cases 5 and 6 show the need to look for L.S.D. and amphetamines at necropsy in deaths of this type, lest some be wrongly attributed to suicide.

Despite the statements of the protagonists of the use of this drug that it is safe, L.S.D. can be dangerous when taken casually—for example, when not taken by selected patients under strict medical supervision and with the use of proper safeguards. The incidence of adverse effects associated with controlled use of the drug by physicians suggested that in medical hands it was an exceptionally safe drug (Levine and Ludwig, 1964).

Summary

Recently there has been an increase in the use of lysergide (lysergic acid diethylamide; L.S.D.) obtained illicitly. Adverse reactions are not uncommon, and six (two fatal) cases are reported.

I am grateful to Professor F. E. Camps, Dr. A. Robinson, and Mr. F. F. Haddock for help with information about some of these cases.

Preliminary Communications

Trephine Biopsy for Diffuse Lung Lesions

Brit. med. J., 1967, **3**, 30–32

Drill biopsy of various tissues by means of a dental drill and cylindrical rotating cutting needle was described by Kirschner (1935). The technique was modified by Christiansen (1940) and further results with this method were reported by Ellis (1947). A high-speed pneumatic drill was used by Deeley (1960). Within the thorax, these authors confined themselves to the diagnosis of peripheral tumours adherent or adjacent to the chest wall, and, despite the theoretical advantages of the procedure over other methods of lung biopsy, interest in it has lapsed because of this limited application. It is our purpose to show how high-speed drill biopsy can be extended to the diagnosis of diffuse pulmonary conditions.

The extremely fast cutting edge provided by the air-drill was found to be effective in obtaining specimens from the lung at necropsy, but the small trephine described by Deeley failed to provide adequate specimens of diffuse lesions from inflated lung. To overcome this difficulty a large trephine with special features was designed by one of us (S. J. S.) and proved successful experimentally and in practice.

INDICATIONS

Indications include diffuse and localized lesions of the lung or pleura where a definitive diagnosis is required for the purpose of treatment, prognosis, or a claim for industrial compensation.

There are no specific contraindications other than bullae, cysts, or aneurysms, but it is wise to avoid patients with a bleeding diathesis or insufficient respiratory reserve to risk a pneumothorax. Some upper-lobe lesions may prove inaccessible and those adjacent to the mediastinum are best avoided.

METHOD

The apparatus consists of a small Desoutter pneumatic drill easily held in the hand and driven by compressed air from a cylinder fitted with a reducing valve. A speed of up to 15,000 revolutions per minute at a pressure of 100 lb./sq. in. (7 kg./sq. cm.) is controlled by a trigger. The spindle of the drill is connected by a Luer fitting to a hollow trephine 7.5 cm. long and 3 mm. in external and 2.1 mm. in internal diameter, with a right-angled smooth cutting edge. The trephine is rifled internally for 5 mm. behind the cutting edge to guide the specimen into its lumen, and fitted with a sharp-pointed keyed stylet projecting 2.5 mm. beyond the end (Fig. 1).

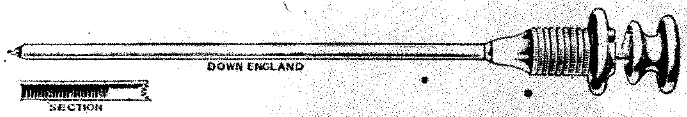

FIG. 1.—Lung biopsy trephine for use with high-speed air-drill. Length 7.5 cm., external diameter 3 mm., internal diameter 2.1 mm. Internal rifling for 5 mm. at end. Sharp-pointed keyed stylet fitted.

The first step is to choose a suitable site with chest radiographs and markers. If the lesion is diffuse and bilateral the most convenient position is usually the eighth right intercostal space posteriorly with the patient sitting across the bed and leaning forward, but an axillary or anterior approach may be used with the patient lying down. Premedication is not usually necessary, but it is essential to demonstrate the apparatus to familiarize the patient with the whistling noise produced by the air-drill. At the same time the patient should be instructed not to move, cough, or breathe deeply during the drilling process, but breath-holding is not necessary.

The trephine, previously sterilized, is flushed with 3.8% sodium citrate, and about 5 ml. of the citrate is left in a 20-ml. syringe. After infiltration with local anaesthetic a small skin incision is made with a scalpel. The trephine, with the pointed stylet in position, is introduced and, unless a specimen of pleura is required, the point is gently pushed through the parietal pleura. The stylet is then removed and the drill is attached to the trephine. The patient is told to keep still. The trigger is pressed and the trephine, revolving at maximum speed, is steadily pushed into the lung almost as far as the hub ; this should take about three seconds. The drill is then detached from the trephine and replaced by the 20-ml. syringe, which is used to provide suction to retain the specimen while the trephine is withdrawn. The specimen is ejected into filter paper in a funnel and the liquid allowed to run through. Finally it is transferred into fixative.

RESULTS

The results of the first 100 consecutive biopsies, performed from 1962 to 1966, are shown in Table I. A successful biopsy is defined as one where adequate material for histological examination was obtained. The first 21 biopsies, mostly of pleura, were performed with the small trephine, and though it proved successful for thickened pleura or solid lung lesions all the attempts to obtain specimens from lung with diffuse lesions failed.

TABLE I.—100 *Biopsies of the Lung and Pleura with a High-speed Air-drill*

	Total	Successful	Complications	
			Pneumothorax	Haemoptysis
		Small Trephine		
Lung	7	3	1	—
Pleura	14	12	—	—
		Large Trephine		
Transitional stage while undergoing development:				
Lung	17	9	6	1
Pleura	12	10	1	1
Final stage with rifling and pointed sytlet added:				
Lung	38	33 (87%)	7	6
Pleura	12	10	—	—
Totals	100	77	15	8

Subsequent biopsies were performed with the large trephine. There was a transitional stage during which modifications to the trephine were reflected in improving results in lung biopsy. Finally, when rifled and fitted with the pointed stylet, 33 out of 38 (87%) lung biopsies were successful at the first attempt, the majority being diffuse lung conditions (Table II).

TABLE II.—*Histological Findings in* 38 *Lung Biopsies With the Large Trephine*

Histological Diagnosis of Biopsy Specimen		
Number attempted		38
Number successful		33
Organizing pneumonia	3	
Lung abscess	1	
Tuberculosis	3	
Sarcoidosis	5	
Asbestosis	2	
Berylliosis	2	
Diffuse interstitial pulmonary fibrosis	2	
Non-specific pulmonary fibrosis	2	
Emphysema	1	
Alveolar proteinosis	1	
Eosinophilic vasculitis	1	
Adenocarcinoma	3	
Squamous carcinoma	1	
Undifferentiated carcinoma	3	
Normal lung	3	

Complications.—Complications were not serious. Routine post-biopsy radiographs showed that pneumothorax occurred in 15% of cases, but it was usually shallow and asymptomatic (Table I). In most instances the lung re-expanded uneventfully, but one patient required aspiration of air to relieve dyspnoea and another two with surgical emphysema needed an intercostal tube. Only one of the eight haemoptyses consisted of more than transient staining. It amounted to 50 ml. and ceased within half an hour. None of the patients complained of significant pain. There was no instance of air embolism or of invasion of the biopsy track by infection or neoplasm.

CASE REPORTS

Case 1.—A 59-year-old male electroplater complained of three months' increasing dyspnoea on exertion. He had a few crepitations at both bases. A chest radiograph (Fig. 2) showed bilateral diffuse nodular shadowing confluent in the hilar regions. Sputum examination for acid-fast bacilli and neoplastic cells was negative and bronchoscopy showed no abnormality. Drill biopsy of the right lower lobe showed distension of the alveolar spaces with granular periodic-acid/Schiff-positive material, the picture being that of alveolar proteinosis (Fig. 3). He improved clinically and radiologically without treatment.

Case 2.—A 45-year-old man who worked with beryllium-copper alloys complained of two years' increasing dyspnoea on exertion, with cough and scanty sputum. There were no abnormal physical

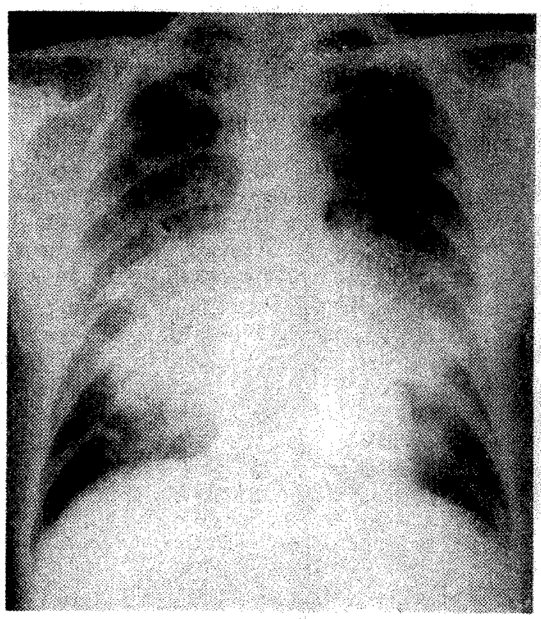

FIG. 2.—Case 1. Bilateral diffuse nodular shadowing confluent in the hilar regions.

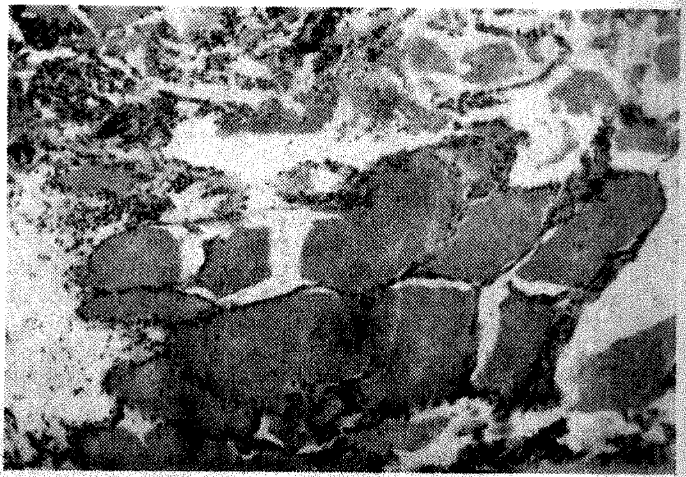

FIG. 3.—Case 1. Alveolar proteinosis. (H. and E. ×90.)

signs. Chest radiography showed bilateral granular and nodular shadowing. A patch test for berylliosis was negative. Drill biopsy of the right lower lobe showed miliary granulomata, the outstanding feature of which was the presence of numerous conchoid bodies. The appearances were those of chronic berylliosis. A shallow right pneumothorax resulted from the drill biopsy but absorbed uneventfully. Treatment was started with corticosteroids, but without appreciable clinical or radiological improvement. He was awarded 20% industrial compensation.

DISCUSSION

The first systematic approach to percutaneous lung biopsy was the needle aspiration method described by Martin and Ellis (1930). This technique produces a small specimen and has chiefly been used by investigators such as Lauby, Burnett, Rosemond, and Tyson (1965) for the differential diagnosis of pulmonary tumours.

In order to obtain a larger specimen for the study of diffuse lesions interest has recently centred on special needles incorporating a cutting mechanism. Manfredi, Rosenbaum, and Behnke (1963) published the results of 18 lung biopsies and advocated the use of a Franklin–Silverman needle. Smith (1964a) reviewed the literature and reported a series of 61 patients who had needle biopsy of the lung—39 with a Vim–Silverman and 22 with a Jack needle. In an addendum further experience with the Jack needle was mentioned, but he subsequently recorded one fatal pulmonary haemorrhage and recommended that the procedure should be performed in an operating theatre with a thoracic surgeon available (1964b). Krumholz and Weg (1966) obtained lung tissue in 56 out of 65 (86%) biopsies with a Franklin–Silverman needle on patients with diffuse lung lesions, chiefly sarcoidosis or interstitial fibrosis. Complications included 12 pneumothoraces, six of which required intubation, and two haemoptyses of 40–50 ml. Another patient with pulmonary hypertension, not included in the series, had a 750-ml. haemoptysis. A disadvantage of their method is that the patient has to hold his breath for 15–30 seconds.

Apart from the work of these authors, most of the reported techniques of needle biopsy have been directed towards a diagnosis of peripheral thoracic tumours, and biopsy of diffuse lung lesions has usually been performed by open thoracotomy according to the method described by Andrews and Klassen (1957). Although this ensures an adequate specimen of lung for histological examination, it entails a major surgical procedure and is subject to the usual complications of thoracotomy.

In our experience high-speed air-drill biopsy with the large trephine has proved successful in obtaining adequate specimens of diffuse lung lesions without the need for major surgery. It is performed at the bedside, thereby saving time in the operating theatre, although it is wise to arrange thoracic surgical cover. From the patient's point of view it is quick and painless, and breath-holding is not required. A further advantage is that the procedure can be repeated if an adequate specimen is not obtained or as a means of assessing the patient's progress.

SUMMARY

One hundred biopsies of the lung or pleura have been performed with a high-speed air-drill over the last four years. A specially designed trephine, 2.1 mm. in bore, proved successful in obtaining adequate specimens from patients with diffuse lung lesions. With this trephine in its final form 33 out of 38 (87%) lung biopsies were successful. Conditions such as sarcoidosis, berylliosis, alveolar proteinosis, and eosinophilic vasculitis were successfully diagnosed. Complications were not serious and pneumothorax, which occurred in 15% of cases, was usually asymptomatic.

We wish to thank the physicians and surgeons of the London Chest Hospital, in particular Dr. E. H. Hudson, for their support. We are indebted to Mr. K. G. Moreman for the photomicrograph and the Photographic Department of the Royal Marsden Hospital for the illustrations.

Medical Memoranda

Agranulocytosis Coincident with Amodiaquine Therapy

Brit. med. J., 1967, **3**, 32–33

Agranulocytosis is recognized as a rare complication of amodiaquine therapy. Love, Foulk, Williams, and Mitchell (1953) reported two cases of leucopenia ; Yates, Leeper, and Fishler (1955) reported a case of pancytopenia ; and Kennedy (1955) described a case of absolute neutrophil leucopenia. Glick (1957) described fatal agranulocytosis following 200 mg. of amodiaquine daily for eight weeks, and Perry, Bartholomew, and Hanlon (1962) an almost fatal reaction with hepatitis and agranulocytosis after 200 mg. daily for seven days.

This paper reports four cases (one fatal) in which agranulocytosis occurred coincident with taking amodiaquine as a malaria suppressive.

CASE 1

A previously healthy 20-year-old man, resident in Papua for only one week, was admitted to hospital with high fever, malaise, and a sore throat. He had taken 150 mg. of amodiaquine once or twice daily for three weeks, that dose having been prescribed in error as a malaria suppressive. He had never taken amodiaquine before, and was not taking any other drug. Haemoglobin was 14.1 g./100 ml., and the total leucocyte count 3,000/cu. mm., with no granulocytes. Bone-marrow aspiration showed an almost complete absence of developing granulocytes. Paul–Bunnell test was negative.

He was extremely ill from the onset, running a high fever and vomiting intermittently. A small blister on the knee developed into a spreading cellulitis from which *Pseudomonas pyocyanea* was isolated, the same organisms also being cultured from the blood stream. In spite of broad-spectrum antibiotics, digitalis, and corticosteroids he died on the fifth day in a state of " Gram-negative shock." Blood counts are shown in the Table.

CASE 2

A previously healthy man aged 30 was admitted to hospital with headache, fever, anorexia, joint pains, diarrhoea, and a sore throat. Haemoglobin was 14.4 g./100 ml., leucocyte count 2,000/cu. mm., with only 2% granulocytes. Thinking that he had malaria, the patient had taken 450 mg. of amodiaquine daily for five days. He had been in Papua for only four weeks, and had taken 300 mg. of amodiaquine twice weekly during this time. He was not taking other drugs, and had not had antimalarials before.

Being allergic to penicillin, he was treated with oxytetracycline, and later, when he developed a painful infected haemorrhoid, erythromycin and streptomycin were added. Fever persisted for 16 days and granulocytopenia for three weeks. He was discharged with a leucocyte count of 4,000/cu. mm., and 30% granulocytes (see Table).

CASE 3

A 57-year-old woman complained of pain in the back and epigastrium for one week and was thought to have cholecystitis. Haemoglobin was 11.7 g./100 ml., and there were 2,800 leucocytes/cu. mm., with 40% granulocytes. One week later, after a further attack of pain, the leucocyte count was 3,200/cu. mm., with an almost complete agranulocytosis. She had been in Papua for one month, and had taken 300 mg. of amodiaquine weekly. She had never taken this drug before, and was not having any other drugs.

She was admitted to hospital and treated with penicillin. On the third day her temperature was 103° F. (39.4° C.) and streptomycin was added. The agranulocytosis persisted, and on the fourth day prednisolone 15 mg. q.i.d. was begun. Two days later the percentage of granulocytes had increased, and by the third week the leucocytes showed a normal distribution (see Table). A Paul–Bunnell test performed in the third week was negative.

CASE 4

A 65-year-old man complained of severe sore throat, malaise, and earache. He was treated with penicillin, but three days later was unable to swallow because of pain. He was admitted to hospital, where haemoglobin was found to be 13.5 g./100 ml., leucocytes 1,100/cu. mm., with complete agranulocytosis. Pus from his inflamed ear gave a profuse growth of *Ps. pyocyanea.* He had been in Papua for 10 weeks, and had taken 300 mg. of amodiaquine weekly, but no other drugs.

He was treated with penicillin and oxytetracycline, but continued to run a fever of up to 104° F. (40° C.) for six days, after which his condition slowly improved. By the eleventh day his count had risen to 5,800/cu. mm., with 47% granulocytes (see Table), and he was then discharged.

Day of Illness	Case 1		Case 2		Case 3		Case 4	
	W.C.C.	G.	W.C.C.	G.	W.C.C.	G.	W.C.C.	G.
1	3,000	(0)	2,000	2%	2,800	40%	1,100	(0)
2	550	(1)	—	—			700	(0)
3	850	(0)	1,600	(2)				
4	600	(0)	—	—			800	(2)
5	650	(0)						
6			1,400	(2)			2,000	12%
8					3,200	(11)		
9								
10			1,300	(8)	3,500	(1)		
11					1,500	(10)	5,800	47%
12								
13			1,600	(2)				
14					1,000	15%		
15								
16			1,600	(5)	3,000	36%		
17								
18			1,600	(few)				
19					6,200	22%		
20			1,500	10%				
23					7,000	65%		
24			4,000	30%				

W.C.C. = Total leucocyte count. G. = Number of granulocytes either as a percentage of the total count or, where figure is in parentheses, total number found after a search for five minutes.

DISCUSSION

In all four cases amodiaquine was the only drug known to have been ingested in the month preceding the illness. In all four the granulocytes were the only elements of the blood to be affected, red cells, other leucocytes, and platelets remaining normal.

It has not been possible to prove that the agranulocytosis was caused directly by amodiaquine. In Cases 1 and 2 the possibility is strengthened by the fact that the drug was taken in excessive dosage (as in other fatal and near fatal cases reported). It is important for practitioners in temperate zones to familiarize themselves with correct dosage schedules for antimalarials.

The three non-fatal cases occurred in the same month, in European persons newly arrived in Papua. This suggests the possibility of an infectious disease or some other factor common to all three, either causing agranulocytosis or rendering them susceptible to the effect of amodiaquine. No such factor could be traced.

The amodiaquine taken by all four patients was Camoquin 150-mg. tablets. Tablets supplied in Cases 2 and 3 were referred to the manufacturer, and were reported to conform with official standards.

The cause of death in Case 1 appears to have been *Ps. pyocyanea* septicaemia, which was not recognized until the patient was in extremis. Corticosteroids did not seem to have a significant influence on the course of the illness, and were not given to two of the patients who recovered.

Thanks are due to Dr. R. F. R. Scragg, Director of Public Health, Territory of Papua and New Guinea, and to Dr. A. Tonakie and Dr. C. H. Campbell for permission to publish cases under their care.

ADDENDUM.—Since this report was written there has been a further fatal case of agranulocytosis in a 47-year-old Australian missionary at Wewak. He was admitted to hospital under the care of Dr. Vaughan with cellulitis of the foot, and had recently suffered from two boils and a paronychia. Bone-marrow and blood examination showed almost complete agranulocytosis, with thrombocytopenia. Despite intensive antibiotic treatment he developed acute gingivitis, pharyngitis, and otitis externa, and died after a few days. Cultures from blood, foot, throat, and ear all grew *Ps. pyocyanea.* He had taken 300 mg. of amodiaquine weekly since arrival in the Territory of Papua and New Guinea ten weeks previously, with an additional 2,100 mg. during the five days prior to admission. The only other drugs taken had been Aspro and tetracycline.

Sudden Onset of Psychosis in Association with Vitamin-B_{12} Deficiency

Brit. med. J., 1967, 3, 34

Psychiatric disturbance due to avitaminosis B_{12} is well documented (Holmes, 1956 ; Wiener and Hope, 1959 ; Fraser, 1960 ; Smith, 1960), but the precipitation of such a situation by folic acid cannot fortunately be common, since the dangers of neurological damage by folic acid in the presence of vitamin-B_{12} deficiency are now well known (Spies and Stone, 1947 ; Israëls and Wilkinson, 1949 ; Conley and Krevans, 1955). The results were so dramatic in a case which recently came to our attention that we feel the details are deserving of record.

CASE HISTORY

A 53-year-old housewife presented in February 1966 with a four-year history of intermittent numbness and tinglings in the arms and legs which had been diagnosed elsewhere at the onset as being due to cervical spondylosis and treated by neck traction with partial relief. After a minor traumatic episode six months before presentation the symptoms had become more pronounced and unremitting and she had also developed weakness of fine movements of the hands. During the last six months she had felt depressed.

On inquiring into her past history it was found that she had been treated by "acid" for anaemia 15 years previously—this was probably hydrochloric acid—and that it had been discontinued after some 12 months. In March 1965 she was admitted to another hospital for hysterectomy for menorrhagia. At this time a blood count showed: Hb 50% (7.4 g./100 ml.) ; P.C.V. 25% ; M.C.H.C. 30% ; W.B.C. 4,000/cu. mm., normal differential ; reticulocytes 6% ; M.C.D. 7.8 μ by halometry ; appearances of film compatible with rapid red cell regeneration with some hypochromia, but macrocytosis not striking. A histidine loading test for formiminoglutamic acid was weakly positive. Blood transfusion, iron, and folic acid were given with good response, but tests to exclude vitamin-B_{12} deficiency were not carried out and she continued taking folic acid, 10 mg. t.d.s., until admission.

On examination she was a fit-looking, well-nourished woman who appeared depressed. There was no clinical anaemia, but glossitis was severe. In the central nervous system she was orientated in time and space. Cranial nerves were normal. Power was generally diminished in all four limbs, especially in the distal muscle groups. She had impaired sense to pinprick of the hands and feet and impaired proprioceptive and vibration senses of the feet and lower legs. Tendon reflexes were symmetrically depressed, the supinator and knee reflexes being absent. Gait and Romberg's tests were normal.

Investigations showed: Hb 12.4 g./100 ml., with normal indices and normal film ; W.B.C. 4,500/cu. mm., with normal differential ; E.S.R. 3 mm. in first hour ; total serum protein 5.7 g. (albumin 3.2 g.). Electrophoresis showed slight increase in β-globulin. Liver-function tests were normal. Pyruvate-tolerance test: fasting, 2.55 mg./100 ml. ; 30 minutes after 50 g. of glucose, 4.0 mg./100 ml. ; 60 minutes, 3.7 mg./100 ml. ; 120 minutes, 2.8 mg./100 ml. The normal blood pyruvate level is 0.5 to 1 mg./100 ml. and after glucose should not exceed 1.4 mg./100 ml.

Four days after admission she suddenly became frankly psychotic with delusions, requiring large doses of chlorpromazine. The mental picture was characterized by confusion with paranoid delusions and auditory hallucinations. She was convinced that others in the ward were saying horrible things regarding her and that she was about to undergo a serious brain operation.

Vitamin-B_{12} deficiency was suspected, and after the injection of cyanocobalamin 1,000 μg. for the Schilling test her mental aberration started to improve within 24 hours, and after 48 hours there was marked improvement. The Schilling test showed only 5.3% excretion of the oral dose in 24 hours, rising to 13.3% after 100 mg. of hog intrinsic factor.

Further investigation by Kay's augmented histamine test meal showed achlorhydria, and a barium meal with follow-through was normal apart from a bald gastric fundus. Bio-assay showed serum vitamin B_{12} 62 μμg./ml. and folate 100 mμg./ml. Xylose excretion was 2.1 g. after a 5-g. dose. Faecal fats were 12.8 g. in the first 24 hours, 7.8 g. in the second 24 hours, and 6.4 g. in the subsequent 24-hour periods.

Within a few days the mental symptoms had completely resolved, and over the ensuing weeks there was considerable symptomatic improvement in the peripheral neuropathy and she had only occasional mild paraesthesiae in the hands and feet. The power has improved, but at the time of writing impaired vibration sense and diminished tendon reflexes were still present.

COMMENT

The evidence of vitamin-B_{12} deficiency secondary to pernicious anaemia seems conclusive from the bio-assay and Schilling test results in this case, though there would also seem to be an element of malabsorption in the small intestine not involving vitamin B_{12}, as shown by the high faecal fat excretion values. The rapid improvement in the mental symptoms after parenteral vitamin B_{12} strongly favours deficiency of this vitamin as the cause of the psychosis, which began with dramatic suddenness at a time when the blood picture was normal and the clinical findings indicated peripheral neuropathy rather than the spinal involvement typical of subacute combined degeneration of the cord. A similar sequence of events was described in three cases by Strachan and Henderson (1965). It was fortunate that the psychosis developed while the patient was under observation in hospital so that treatment could be instituted promptly. We feel that this case illustrates once again the danger of prolonged folic acid therapy without prior exclusion of vitamin-B_{12} deficiency.

We wish to thank Dr. J. W. Aldren Turner for permission to publish details of this case.

Current Practice

Clinician's Approach to Respiratory Viruses

NEVILLE C. OSWALD,* T.D., M.D., F.R.C.P.

Most clinicians dismiss the laboratory aspects of virology as being too difficult. They are aware that considerable advances have been and are being made and that some hundreds of viruses, many of which are pathogenic to man, can be positively identified by one means or another. Unhappily, these advances have been achieved by techniques which are not readily understood by clinicians, who are often at variance with virologists when it comes to the collection of specimens and the interpretation of results. Maybe they are at fault in failing to appreciate the difficulties of viral identification and in being intolerant of delays in the reporting of results which perforce are frequently negative. Whatever misunderstandings there may be, the fact remains that the science of virology is firmly in the grip of virologists and epidemiologists at the present time. Clinical virology as a subject is virtually non-existent, principally because of the lack of contact between clinicians and virologists and of course the lack of antiviral remedies. In practice this means that clinicians are useful chiefly for gathering material for field trials or for supplying random samples to be tested at leisure for the purpose of prevalence studies. Incidentally this situation is not peculiar to Britain.

None can deny the clinical importance of respiratory viruses, in that they contribute to the vast problem of acute respiratory disease which is responsible directly or indirectly for roughly one-quarter of all visits to general practitioners, one-quarter of all sickness absence in the working population, and one-tenth of deaths from all causes. Indeed, the sheer weight of clinical experience qualifies practising physicians who possess no more than a rudimentary knowledge of laboratory techniques at least to ponder on the problems confronting them. Their main concern is with the rapid identification of organisms when it may have some bearing on treatment. This is certainly not the case in the great majority of viral illnesses, which are comparatively trivial and of short duration. For example, Hope-Simpson (1966) estimates that only one patient in twenty with a cold in the head visits his doctor. Should pneumonia develop, the situation is quite different. Then any positive information is useful, provided that it is forthcoming while the disease is still active. Evidence of infection by influenza virus immediately raises the question of the extent to which the virus is responsible for the degree of illness and the extent of the consolidation, and of the possibility of staphylococcal superinfection. A patient with a positive test, for example, for adenovirus or respiratory syncytial (R.S.) virus may be saved from unnecessary antibiotic therapy when the pneumonia is slow to clear. Pneumonias caused by the mycoplasma, rickettsia, and psittacosis groups respond favourably to the tetracyclines; alas, they remain undiagnosed for the most part under existing conditions. This is particularly unfortunate in the case of mycoplasma infections, which probably account for about 10% of all primary pneumonias, with much higher figures having been recorded in children and young adults (Chanock *et al.*, 1963). High titres of serum antibody often develop early, and if facilities existed for the speedy testing of single specimens of blood, treatment with dimethylchlortetracycline could be started without undue delay, in anticipation of a fourfold rise in titre between the paired sera.

The Viruses

The term "respiratory viruses" is open to several interpretations. Some—for example, enteroviruses, chicken-pox, and measles—frequently propagate in the upper air passages and are disseminated from them without necessarily causing respiratory symptoms. Others are established agents of acute respiratory disease, of which the most important to be discovered so far are the influenza and parainfluenza viruses, adenoviruses, respiratory syncytial virus, rhinoviruses, and the Coe strain of Coxsackie virus. There are also the somewhat larger rickettsia, psittacosis, and mycoplasma groups, though of course they are no longer regarded as true viruses. The principal means of identification of these organisms are by cultural methods, electronmicroscopy, and immunological techniques.

The Table shows the current standard culture media and the times taken for isolation. Fairly rapid primary isolation can sometimes be achieved, with the exception of rhinoviruses and *Mycoplasma pneumoniae*, but further tests for typing are essential before a firm opinion can be given. While cultivation is fundamental to the study of viral illnesses, it has many disadvantages in clinical practice. Respiratory secretions need to be collected within four days of the onset of symptoms (Higgins *et al.*, 1964), and even then the number of positive results is unlikely to exceed 30% (M.R.C., 1965). A final report, including typing, is rarely available within a fortnight from the taking of the specimen. A formidable variety of tissue cultures needs to be maintained. For these reasons existing cultural methods have little to offer for the day-to-day management of patients in general hospitals with acute respiratory infections.

Time Taken for Isolation of Organisms and Media Used. Specimens Taken at 1–5 Days. Typing Time Additional

Organism	Isolation	Medium
Influenza	3–21 days	Eggs; monkey kidney
Parainfluenza	3–21 „	Monkey kidney
Adenovirus	3–30 „	HeLa cells
Rhinovirus	1–2 months	Embryo kidney WI.38
R.S. virus	5–21 days	HeLa cells
M. pneumoniae	1–3 months	Agar; broth
Q fever	4–14 days	Eggs
Psittacosis	5–30 „	Mice; eggs

Electronmicroscopy presents exciting possibilities for early diagnosis, particularly since the introduction of negative-staining techniques (Smith and Melnick, 1962; Williams *et al.*, 1962). It is useful in differentiating groups of viruses—for example, myxoviruses, adenoviruses, and rhinoviruses; it cannot be used to distinguish between members of groups. It has the great advantage that, should virus particles exist in sufficient numbers, group identification can be carried out quickly. The classical example, of course, is smallpox, which can be recognized within a quarter of an hour of the receipt of a specimen of secretion (Cruickshank *et al.*, 1966). Whether this method will ever be usefully applied to acute respiratory infections remains to be seen. Unfortunately, respiratory viruses tend to be comparatively sparse, making identification of extracellular forms in respiratory secretions very difficult. Examination of ultra-thin sections of secretions, with a view to seeing developing particles within the cut cells, may eventually be a fruitful if laborious technique. Positive results are clinically most desirable in pneumonia, so that specimens of sputum would seem to be the most appropriate, taken during the early stages when the infected cells are most likely to be shed.

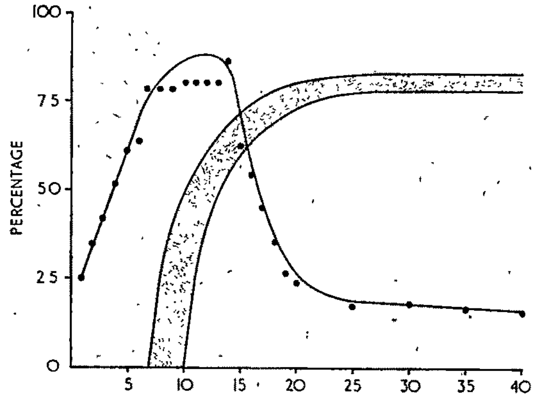
* St. Bartholomew's Hospital, London E.C.1, and Brompton Hospital, London S.W.3.

Various immunological tests are currently available, of which the complement-fixation test, despite its disadvantages, remains a standard laboratory procedure. It can be applied to infections by all the organisms under discussion, with the exception of rhinoviruses, with a view to determining a rise in titre of antibodies which takes place usually between 7 and 21 days from the onset of symptoms. The shaded area in the Chart indicates the likelihood of finding a significant titre according to the day of illness. The area rises to a figure of 75–80%, which varies to some extent with the organism tested. The continuous line in the Chart shows the percentage of patients in hospital with pneumonia according to the day of illness, and demonstrates that the great majority of them are in hospital during the time that the titre would be expected to be raised.



Percentage of patients in hospital with pneumonia according to day of illness. Based on 350 consecutive patients admitted to St. Bartholomew's Hospital in 1963–5 with a diagnosis of primary pneumonia. Median hospital stay 14 days. Shaded area indicates possible percentage of positive complement-fixation tests by days of illness for the common respiratory viruses.

Other immunological tests exist which are not yet generally applicable to the range of respiratory viruses. Fluorescent antibody staining of secretions shows promise (Hers, 1963) and has been developed for influenza virus (Liu, 1956). Non-specific fluorescence causes difficulties, but the method has the great advantage that it is immunologically specific for the viruses tested. The possibility of haemabsorption of cells in sputum is being studied with a view to the early diagnosis of infection by myxoviruses. Gel diffusion has already been successfully used to identify smallpox antigens in secretions (Dumbell and Nizamuddin, 1959). It has also demonstrated antigens of laboratory-grown respiratory viruses when the viruses are available in concentrated form. The low concentration of virus in respiratory secretions has so far precluded its application to acute respiratory disease.

Clinician's Dilemma

Clinicians regard respiratory virology as something of an enigma at the present time. How far should they become involved in it? Should they become involved at all? If they should, how should they set about it? Few hospitals have their own virus laboratories, most of the work being done in the 60 regional and area laboratories of the Public Health Laboratory Service (P.H.L.S.). The P.H.L.S., a successor of the Emergency P.H.L.S. of the second world war, exists "to make a continuous study of how communicable microbial diseases are spread and what advice may be offered about how to control them," and "the duty of the service is to gather as good a sample of relevant information as can be secured and dealt with" (Howie, 1965). This has been the policy up to now—namely, that the virological resources of the country have been directed primarily to epidemiology, and nobody can blame the service, which is short of both virologists and technicians, for apparent delays in the reporting on specimens from individual patients. However, a sense of urgency is rapidly developing. More viruses are being discovered, more is being learnt of their behaviour, and rapid methods of identification are being devised. Overshadowing these considerations is the probable development of specific antiviral compounds in the very near future.

Already drug houses are pressing for clinical trials. The testing of compounds will raise considerable problems. Quite apart from their possible toxicity and range of potency, trials will have to be conducted in naturally occurring outbreaks with all the uncertainties of early diagnosis, and in voluntarily infected individuals, bearing in mind the difficulties in inducing infection and the risks involved. Clinical and statistical appraisal will be far from easy. These matters will need to be left in the hands of experts in the first instance. How hospital clinicians without immediately available virological facilities will become involved remains to be determined. The time is not yet ripe for the establishment of routine virus laboratories in general hospitals, nor does the staff exist to man them. However, some bridges must soon be erected between hospitals and the virologists' strongholds. These might take the form of laboratory technicians trained in the collection of specimens in the first instance. Beyond that lie token laboratories under the general supervision of virologists, the day-to-day work being carried out by senior technicians.

For more ambitious schemes, serious thought should be given to the extent to which Ph.D.s can be entrusted with routine laboratory work. Those clinicians who have been privileged to visit virus laboratories cannot fail to have been impressed by the continuous attention to detail which is necessary if disasters are to be avoided. A blown fuse to a refrigerator or the changing of a junior technician can wreck a month's work. There would seem to be much in favour of training more Ph.D.s for these responsibilities, thus leaving medically qualified virologists freer to concentrate on their special interests.

Conclusion

It seems that clinicians will become increasingly involved with respiratory virology. Already virus tests can assist materially in the management of individual patients. The hope is that when effective antiviral compounds become available clinicians will be afforded the opportunity to use them intelligently.

My thanks are due to Dr. R. B. Heath for his comments on this article.

TODAY'S DRUGS

Aerosols in Asthma and Vaccines

The Committee on Safety of Drugs publishes leaflets in its Adverse Reactions Series from time to time. Number five of this series has been published recently, on reactions to aerosols in asthma and to vaccines. The text is given below.

Aerosols in Asthma

A small number of reports of sudden and unexplained deaths of asthmatic patients has reached the Committee. In some instances the circumstances of the deaths were strongly suggestive of overdosage from aerosols containing bronchodilating drugs. Moreover, recent reports in the medical press suggest a possible link between the excessive use by patients of such aerosols and a recorded rise in the death rate from bronchial asthma. This possibility is still under investigation.

In proper dosage bronchodilating drugs given by inhalation are of great value to sufferers from asthma. However, excessive dosage does not increase the degree of relief obtained from these preparations and may be positively dangerous. Prescribers are advised to give patients careful instruction in the use of aerosols for the relief of asthma and to warn them of the dangers of excessive use.

The Committee on Safety of Drugs wish to remind prescribers of the possibility of overdosage with aerosols containing bronchodilating drugs for the relief of asthma. Overdosage is particularly likely to occur with *pressurized* aerosols.

Vaccines

The Committee on Safety of Drugs wish to draw the attention of doctors to the importance of reporting adverse reactions to vaccines and other immunological agents. Such products fall within the Committee's definition of drugs and suspected reactions to them should be reported on yellow cards.

Trivial reactions, such as slight pyrexia or local tenderness, need not be reported. Neither is it necessary to report morbilliform rashes after measles vaccine. Such events as hyperpyrexia, meningism, prolonged drowsiness, and convulsions should be reported on yellow cards.

In the report, the name of the manufacturer and the batch number of the vaccine should be given. It would also be helpful to record the time interval between inoculation and the occurrence of the reaction.

If there is any doubt whether a reaction is serious enough to warrant a report—*report it.*

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Cardiac Catheterization after Myocardial Infarction

Q.—*Are there any indications for intracardiac catheterization immediately after a coronary thrombosis?*

A.—In the vast majority of patients there is no indication for intracardiac catheterization after a myocardial infarction. Very occasionally, however, the question of surgical treatment of a complication such as a ruptured interventricular septum or mitral incompetence (due to malfunction of the papillary muscles) may arise. Under these circumstances cardiac catheterization and angiocardiography might well have to be performed to confirm the nature of the complication and to determine its severity.

Slow-release Corticosteroids in Hay-fever

Q.—*Is there a place for injections of slow-release, long-acting corticosteroids in the treatment of hay-fever?*

A.—Hay-fever is as a rule an inconvenient disorder rather than a disabling one. Most patients can obtain adequate relief with antihistamine drugs or nasal inhalation of preparations containing a small quantity of corticosteroid derivatives. Others may be relieved by desensitization with pollen extract before or during the season.

Slow-release, long-acting corticosteroids have been reported to be an effective form of treatment.[1] No controlled trial, however, has been carried out to confirm this. Though a single injection of corticosteroid is unlikely to be harmful, it temporarily suppresses the adrenal glands and its therapeutic effect cannot be relied on. It might be justifiable to use this form of treatment in a patient who had bad hay-fever and who wished to be free from symptoms for some special purpose, such as taking an examination. But a short course of oral corticosteroids would be equally effective and the dose more easily controlled. In my opinion the use of systemic corticosteroids is rarely justified in uncomplicated hay-fever.

Treatment of Bell's Palsy

Q.—*What is the present-day treatment of Bell's palsy? Have corticosteroids any place?*

A.—Many patients with Bell's palsy in whom there is physiological block without denervation make a complete and fairly rapid recovery. Matthews[1] found that 65% of a series seen at hospital within six days of the onset fell within this group. In the group with denervation improvement may not start for three to four months, and in nearly all patients incomplete and associated movements are common. Tests for excitability in the facial nerve are claimed[2] to distinguish between physiological block and denervation as early as 72 hours after the onset of facial palsy, and galvanic stimulation of the tongue[3] is also used in early differentiation. Administration of cortisone,[4] galvanic stimulation of the facial muscles,[5] and repeated cervical sympathetic blockade[6] have all been used in controlled trials and are reported to have no beneficial effect. Recently Taverner and his colleagues[7] have used corticotrophin gel given by intramuscular injection for ten days. Of 77 patients treated 64 recovered completely and 13 developed denervation. From previous studies they report that the expected results in 77 successive patients with Bell's palsy would be 47 complete recoveries and 30 with denervation.

Gammaglobulin in Early Pregnancy

Q.—*How often should gammaglobulin be administered in early pregnancy as a prophylactic against rubella?*

A.—Evidence suggests that one injection of gammaglobulin is a prophylactic against rubella. It may prolong the incubation period if the disease is to appear. It is not yet certain that it diminishes the number of foetal abnormalities, but it seems likely.[1]

NEW APPLIANCES

Inexpensive Heat-exchanger System for the Rygg Bag Oxygenator

Mr. **DONALD LONGMORE**, consultant physiologist, National Heart Hospital, Mr. **DONALD ROSS**, consultant surgeon, National Heart Hospital, and Mr. **DEREK RAY**, research engineer, British Heart Foundation, write: Having successfully used the Rygg bag in over 140 human perfusions, we felt that we had not fully taken advantage of the low prime of this oxygenator, for we were employing a separate heat exchanger the large volume of which often made it necessary to use blood in the prime. The low prime of the Rygg bag with the coil described makes it possible to use a clear fluid prime.

The advantage of disposability is lost if difficult-to-clean multi-tube stainless-steel heat exchangers have to be used. Disposable stainless-steel heat exchangers were found to be satisfactory, but they had a considerable resistance to flow and were prohibitively expensive. Accordingly, we investigated other techniques for maintaining temperature while on perfusion. Since we have used hypothermia below 34.5° C. only once in the last hundred bypass cases, a high-thermal-capacity heat exchanger was not thought necessary.

Microwave heating of the blood was rejected because of its complexity. Radiant heat was also rejected because of the risk that it would dry the blood film left on the sides of the bag as the levels changed. Therefore the simple device for immersion in the blood in the bag was designed (Fig. 1). The two collecting-chambers on the arterial side of the bag are slit with a sterile knife on the connector side of the bag, and the autoclaved coils* are then threaded carefully through these slits, avoiding contamination against the outside of the bag. A thermometer is placed in the fluid entering the coils from the heat reservoirs, so that the critical upper limit of temperature of 42° C. is never exceeded. Slitting of the bag is not a disadvantage, for, although it increases the prime slightly, this increase is nullified by the immersed volume of the coils.

Even if the coils are not used, we routinely pierce the bag for blood sampling and never proceed to perfusion without venting all three chambers of the bag. Venting of these chambers avoids the possible risk of embolism, which could result if both inlets to the defoaming chamber were blocked by drip nozzles.

The prototype coil itself was made from standard ¼-in. (6-mm.) 16-gauge copper tube, hand-formed with loosely wound coils. These coils were chromed before they were compressed to their final form. Experimentally we have shown that with a blood flow of three litres, a gradient of 10° C., and a fluid flow of 0.75 litre the heat transfer is 6,000 calories/minute. The performance of these coils is shown in the cooling curve for a 63-kg. patient with a 3.8 l./minute flow (Fig. 2). This was the one patient in whom hypothermia was instituted; the rate of cooling is shown with the coil perfused with ethylene glycol, starting at +2° C. and ending at +18° C. as the cold reservoir warmed. The room temperature was 22° C. If cooling is instituted by using the coil in this way it is necessary to have a brief circulatory arrest while a conventional heat exchanger is added to the circuit to assist rewarming.

This device is commercially available in stainless steel; we think it will be a worthwhile adjunct to the use of this excellent oxygenator until such time as Polystan Ltd. can produce a four-layered bag with heat-exchange surfaces on both sides of the blood compartment.

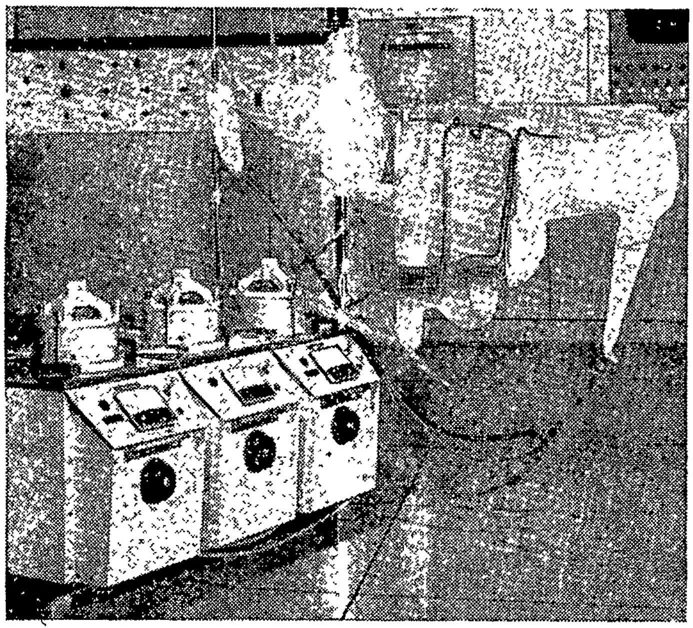

FIG. 1.—Cooling coils are shown against the Rygg bag in the position they would occupy. The pumps are National Heart Hospital pattern—Belmedical driven roller pumps, adjustable for occlusiveness with split heads for immediate tube-changing. The trolley is made from speed frame Dexion.

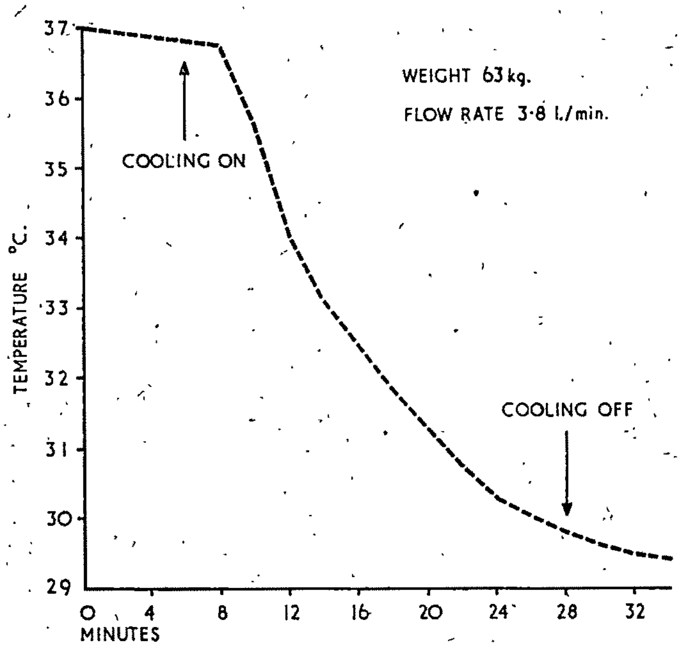

FIG. 2

---

* These coils are commercially available from Belmedical, Farnham Road, Slough, Bucks.

Book Reviews

Medical Care in Developing Countries

Medical Care in Developing Countries. Edited by Maurice King, M.A.(Cantab.), M.R.C.P. (Lond.). (30 chapters+appendix ; illustrated. 30s.) London : Oxford University Press. 1966.

In this book, which embodies contributions to a symposium on the subject held in Makerere, Uganda, the problems of medical care in emergent countries are considered in a very practical manner by authors skilled in the field and culled from university, health authorities, and lay specialists. Despite this diversity of talent, the book is homogeneous and represents a collaboration between academic and practical points of view which is unique.

There are 30 chapters, including an excellent hard-hitting introduction by the editor, Dr. Maurice King, who defines medical care as "the study of how the fundamental knowledge embodied in medicine and public health can best be applied to the benefit of a community." He enunciates three major propositions on which the book is based. Medical care in developing countries differs sharply from medical care in industrial ones ; its main determinant is poverty rather than a warm climate ; it is a subject of major importance, and it is possible to gather together enough knowledge to determine how to deal with the challenge it creates. The 12 axioms which follow from these propositions should form the philosophical and practical basis for those concerned in planning medical care, whose aim, as Professor Macdonald points out in his foreword, must be to "hasten the advancement of health, which is a universal object of all developing countries."

The second chapter deals with the fundamental question, How in rural areas in particular can preventive and curative services be planned to provide the maximum return in human welfare from limited resources of money and skill ? The ideal peripheral unit in a health service may not always be the so-called "health centre," particularly if it is built for occupation by a doctor in countries where doctors are few and in great demand, and are usually unwilling, short of compulsion, to work in rural areas. Well-trained auxiliaries may provide a temporary solution. Rex Fendall, from his own vast experience, offers a more realistic approach to the health centre, which he defines as "a unit which provides a family with all the health services it requires other than that which can only be provided in a hospital." Such a centre can be adjusted to the particular needs of a given locality, allowing for variables such as population density and the availability of trained staff, medical supplies, and visiting specialists.

Other chapters are concerned with the importance of collecting and interpreting epidemiological data, and with "community diagnosis," which implies knowledge of the ecology of particular diseases in relevant geographical areas, in turn demanding some understanding of the interplay between the infective agent and genetic, nutritional, cultural, agricultural, and other factors. The significance and importance of health education is pointed out with authority by Dr. Bennett, who writes with much practical experience. The training of auxiliaries and the relation between them and medically qualified personnel are discussed in detail. Medical schools in developing countries must be more closely associated with such teaching.

Chapters on administration and teaching, progressive patient care, and architecture of hospitals and health centres are followed by a description of the "sorting" systems in common use in outpatient clinics in the tropics. The importance of separating adults and children is stressed. Professor Jelliffe points out the very high proportion of children in tropical populations and discusses the diagnosis and management of his "top ten" diseases of childhood as seen in Makerere : pneumonia, ancylostomiasis, measles, pertussis, pyogenic and tuberculous meningitis, prematurity, sickle-cell disease, poliomyelitis, neonatal sepsis and septicaemia, and neonatal tetanus. There are very interesting and authoritative discussions of protein calorie malnutrition, kwashiorkor, and diarrhoeas in childhood. Dr. Morley contributes an excellent account of the philosophy, methods, and results of his "under-fives" clinic in Ilesha, Western Nigeria. Immunization campaigns are discussed by Dr. Stanfield in a practical and extremely useful manner.

The book also covers family planning, maternity care and the use and training of midwives, psychiatric problems, tuberculosis, blood transfusion, various hospital, laboratory, and training techniques (including medical records and teaching aids), and an account of supporting services such as the laundry and the workshop. Useful appendices follow, designed for the direct use of the doctor and the health planner in the tropics.

When the next edition of this remarkable book appears, as it must, it is to be hoped that it will include discussions on mass vaccination campaigns, the importance of medical field units for surveys of endemic disease, and the health problems engendered by the socio-economic developments which are the hallmark of the developing country and which are adding problems of population movement and interchange of infections to the already almost intolerable load the health services of these countries are expected to carry.

Everyone interested in the medical problems of developing countries should read this book. So should those concerned with general practice in the sophisticated world, in which so many problems are similar and where the idea of "community diagnosis" is certainly not academic.

BRIAN MAEGRAITH.

Bicentenary of Leeds Infirmary

The General Infirmary at Leeds. Vol. 1. The First Hundred Years. 1767–1869. By S. T. Anning. (Pp. 107+xii ; illustrated. 30s.) Edinburgh and London : E. & S. Livingstone. 1963.

The General Infirmary at Leeds. Vol. 2. The Second Hundred Years. 1869–1965. By S. T. Anning. (Pp. 188+xii ; illustrated. 42s.) Edinburgh and London : E. & S. Livingstone. 1966.

This month the General Infirmary at Leeds celebrates the bicentenary of its foundation. Fortunately the infirmary records since its inception have been preserved, thereby enabling the author to produce two books which constitute a well-written historical account.

The first volume covers the period from 1767 to 1869. The infirmary was located first in Kirkgate. Its foundation was not so much a result of the citizens' social conscience but rather as an economic necessity for providing medical care for the town, which was at that time rapidly developing its cloth and woollen industries. The first infirmary was, indeed, a conversion of Mr. Andrew Wilson's house, but it was soon necessary to move to a site near the Mixed Cloth Hall. In the late 1850s, even with 128 beds, the infirmary was so pressed for facilities that a move to larger premises was inevitable. The move took place in 1869, to the present site of the infirmary.

The second volume covers the period from 1869 to 1965. From the weekly records, reports, portraits, and plans the author has produced not just a catalogue of historical events but an absorbing account of the infirmary, its people, founders, committee members, staff—lay, medical, nursing, and ancillary—its buildings and departments, its work, and also the medical school. The founders obviously had good business acumen, which ensured the development of the infirmary.

Institutions become great because they are served by great people. There is no doubt that Leeds certainly had its share of great men. The period from 1866 saw rapid advances in surgery. There is a full description of life in the infirmary during this time, and of how the methods of antisepsis were introduced and how they were abandoned in 1880 with a recognition of the need for aseptic procedures. The change was largely accepted as a result of Moynihan's great influence.

There was an awareness, even in early times in this great provincial centre, of the need of forward planning. As early as 1860 the affiliation and amalgamation of science and medicine were appreciated. For the future the leaders of the infirmary see the necessity of locating their new medical centre in proximity to the university. The infirmary authorities also recognized in the early 1800s the need for a high standard of nursing. In

1889 the infirmary received Miss Nightingale's commendation, and with the Leeds University in 1921 the first Diploma of Nursing in Europe was established.

These two volumes, excellently written and illustrated, will not only be of interest to those who have worked in the infirmary but also to those interested in the history of hospitals and social services of the past 200 years.

JOHN REVANS.

Reflections on the Development of Medicine in America

Medicine in America. Historical Essays. By Richard Harrison Shryock. (Pp. 346 +xviii. 60s.) London: Oxford University Press. 1967.

Professor Shryock is known for his thoughtful writings on the social, cultural, and scientific aspects of medical history. In this volume he has gathered together a selection of his essays and added a preliminary chapter containing a "pilot study" of American medical history; though this synopsis is useful medical readers will note a few important gaps.

The essays are grouped under five headings—period pieces, personal and public hygiene, the medical profession, medical thoughts and research, and historiography. There is, unavoidably, a certain amount of overlapping. The author is a philosophic historian and states that his writing "to avoid distortion, must be largely impersonal, rarely dramatic, and never glamorous." Fortunately it is very difficult to be strictly impersonal in writing medical history, so that in the chapters dealing with medical thought we find an interesting account of Cotton Mather's advocacy of inoculation against smallpox, and are told about the remarkable anticipation of part of Darwin's hypothesis by that strange genius William Charles Wells (who incidentally spent most of his professional life in London). In the same group of essays will be found a very judicial estimate of Benjamin Rush's influence upon American medicine.

In the group of "period pieces" will be found an unusually interesting account of "Medical Care in the Old South" in which readers may be surprised to learn that mortality was greater among the free than among the slave negroes. The account of the muddled medical services during the early part of the American Civil War is depressing, though it was not worse than occurred in the Crimean War.

The chapters on popular and public health movements, and the campaign against tuberculosis in America, remind one of very similar movements in Britain. In the chapter on "Women in American Medicine" I was surprised to find that the proportion of women graduates in medicine in the United States is less than it is in Britain and other European countries. The author's view "that American opposition to the entrance of women into medicine was the fact that it was associated with a strong feminist movement" does not seem a sufficient reason.

Under the section of "historiography" the author gives useful advice on some little known or insufficiently used medical sources, and urges that historians should study more closely the history of science in America. The final chapter discusses the interplay of social and internal factors in modern medicine; most medical historians make this interplay obvious, but few have discussed the matter so philosophically.

ZACHARY COPE.

Do Delinquents "Grow Out of It"?

Deviant Children Grown Up. By Lee N. Robins, Ph.D. (Pp. 351+xiv. 68s.) Edinburgh: E. & S. Livingstone. 1966.

This is an important book which reports a 30-year follow-up of deviant children. A team of doctors and social workers under the guidance of Professor Lee N. Robins, Ph.D., Professor of Sociology in Psychiatry, Washington School of Medicine, carried out this research over a period of eight years. It consisted of locating and interviewing 624 men and women, 524 of whom had been referred 30 years previously as children or adolescents to the St. Louis Municipal Psychiatric Clinic in Missouri.

This research is almost unique owing to the fact that 90% of the adults were located after 30 years and 82% were interviewed. The social records of 98% were scrutinized, which involved searching national service and veteran, welfare, and hospital records, credit bureaux, and driving licence registers, police and prison files. The author points out that they were extremely fortunate in being able to cross-check with so many social sources, as often these records are not made available to research workers.

The prime aim of the study was to determine the adult performance of the 406 antisocial children and the 118 who had been referred for other reasons. 100 controls of similar age, I.Q., and social status were added.

Over a six-year period all children who were referred were studied, omitting those with I.Q.s under 80, negroes, and those who, at the time of referral, were over the age of 18. 28% received psychiatric treatment in the clinic. 50% were later institutionalized following appearance in juvenile courts, as against only 6% of the controls. When located, 71% of the adults had at some time or other been arrested. 86% admitted sufficient facts for psychiatrists to deem them sociopathic, only 7% denied all offences.

It was possible to correlate other forms of psychiatric illness in the adults with the symptoms that had been noted at the time of referral. Both alcoholics and hysterics had, in childhood, shown antisocial symptoms; this was also true of those who later developed schizophrenia. Children who were fearful and withdrawn were no more likely to develop psychiatric illness than the controls. There were no characteristic findings in childhood for those who later developed manic-depressive illness or anxiety neurosis.

For the sociopath the main predicting factor was the number of offences before referral and acts of aggression. Of the non-antisocial symptoms slovenliness and enuresis over the age of 6 were commonly associated with a later development of sociopathy. Having a delinquent father was the only childhood variable which correlated with persistent antisocial trends despite increasing age. Parental rejection and overly strict parents did not, in this study, predict sociopathy.

Child guidance clinics tend to attract referrals according to the preoccupations of the staff, so that not all clinics have the same proportion of antisocial children. The present fluidity of the American cultural background is not universal nor are the legal proceedings, so that it cannot be assumed that the findings of this group will necessarily be repeated elsewhere. This does not, however, detract from a remarkably fine piece of research.

This book is highly commended to all concerned with delinquents, adult and juvenile, and in particular to those sociologists and psychiatrists who are concerned with the prevention of crime.

R. F. BARBOUR.

Books Received

Review is not precluded by notice here of books recently received.

Equipment for the Disabled. An Index of Equipment, Aids and Ideas for the Disabled. 2nd edition. Edited by Margaret Agerholm, M.A., B.M., B.Ch.Oxon. (4 loose-leaf volumes; illustrated. £7 7s.) London: National Fund for Research into Crippling Diseases. 1967.

Plumbismo Cronico Ocupacional en Nuestro Medio. By Dr. Guillermo del Carpio. (Pp. 135. No price given.) Lima, Peru: Medicina del Trabajo. 1966.

Olfaction and Taste 2. Edited by T. Hayashi. (Pp. 835+viii; illustrated. £10.) Oxford: Pergamon. 1967.

Scientific Foundations of Surgery. Edited by Charles Wells, C.B.E., S.Pk., F.R.C.S., Hon. LL.D., and James Kyle, M.Ch., M.B., F.R.C.S., F.R.C.S.I. (Pp. 629+xix; illustrated. £6 6s.) London: William Heinemann. 1967.

The Unquiet Mind. The Autobiography of a Physician in Psychological Medicine. By William Sargant. (Pp. 240+xvi; illustrated. 30s.) London: William Heinemann. 1967.

Le Indicazioni Extraneurologiche Dell'elettromiografia. By Carlo Serra. (Pp. 544; illustrated. 12,000 lire.) Naples: Acta Neurologica. 1966.

The Prevention of Cancer. Edited by Ronald W. Raven, O.B.E., T.D., F.R.C.S., and Francis J. C. Roe, D.M., D.Sc., M.C.Path. (Pp. 397+xiv. £6.) London: Butterworth. 1967.

Hamilton Bailey's Demonstrations of Physical Signs in Clinical Surgery. 14th edition. Edited by Allan Clain, M.B.(Cape), F.R.C.S.(Eng.). (Pp. 627+x; illustrated. 75s.) Bristol: John Wright. 1967.

Vitamins and Hormones. Advances in Research and Applications. Vol. 24. Edited by Robert S. Harris, Ira G. Wool, and John A. Loraine. (Pp. 746+xviii; illustrated. £6 8s.) New York and London: Academic Press. 1967.

Neurological Problems. Edited by Jerzy Chorobski. (Pp. 444+xi; illustrated. 80s.) Oxford: Pergamon. 1967.

Clinical Orthopaedics and Related Research. No. 47. Edited by Anthony F. DePalma. (Pp. 256+x; illustrated. 60s.) London: Pitman. 1967.

Middle Articles

IS THERE AN ALTERNATIVE?

One of the main recommendations of the Porritt Report[1] was the creation of area health boards—authorities which would be responsible for the administration and co-ordination of all the medical services in any one area. In the report's view, " the preventive and personal health services can only be effectively integrated with the family doctor and hospital services by transferring them (services and staff) to the area health boards." At present a Royal Commission is considering the future structure of local government in England, while the Seebohm Committee is considering the future of some of the local authority services. In her article Miss Elizabeth Burney considers the possible relevance of changes in local government to some suggested changes in the health services.

Local Government Reform and the Health Services

ELIZABETH BURNEY, M.A., B.LITT.*

Brit. med. J., 1967, 3, 41–42

By the end of 1968 a Royal Commission will have published its blueprint for modernizing the structure and functions of local government in England (a separate commission sits for Scotland; Wales, for rather inadequate reasons, has been excluded). By the mid-1970's there is every chance that a profoundly reformed system will be in operation. Naturally the size and utility of the local authority health department is being reviewed along with everything else. But, still more important for the health services as a whole, the new structure could provide the long-discussed but little-sought opportunity for unifying the three branches comprising hospitals, general practice, and the community health services. The key point is that this could now take place under local authority leadership, instead of local government merely running the third branch, as it does at present.

This may at first seem far removed from local government reform, which is concerned in the first place with the optimum size of the elected unit. But size is meaningless unless related to functions; indeed, one very obvious difficulty is that each separate function of local government might ideally operate under slightly different circumstances, so that every solution is something of a compromise. But the pattern that is expected to emerge is likely to be similar to that already established in Greater London (also excluded from the current review). Large "first tier" authorities will probably deal with such things as town planning, transport, education, and possibly housebuilding. Within these areas smaller "second tier" authorities would deal with more localized community services, such as welfare, parks, and refuse collection.

"Regional" Units

What size would these new authorities be likely to be? It is fashionable to talk of the largest units as "regional," but this word means different things to different people. Some people (including myself) would prefer these to be as large as possible, so that they would not be many more in number than the present economic planning regions—perhaps only a dozen in the whole of England and Scotland. Others (including officials at the Ministry of Housing and Local Government) have been encouraging the Royal Commission to think in terms of the largest unit being keyed to the major cities and their hinterlands, in a scheme which might eventually produce outside London 20 to 30 "city regions," each averaging over two million people. In any case the actual population size in relation to area is likely to vary widely in different parts of the country. The second-tier authorities are also bound to vary in size, but it is likely to be agreed that for effective contact with their populations they will have to be considerably smaller than the 200,000-population London boroughs. In country areas ease of communications rather than numbers of people served might be the governing factor.

The purpose of all this is not only to increase efficiency but to strengthen local democracy by creating local councils which can be seen to be functioning in a way that is relevant to the needs of modern society. This must mean, among other things, that local authorities regain some of their independence from trivial administrative control from Whitehall (though not from effective quality control), together with the financial means to exercise that independence. For example, it has been argued that petrol tax should be levied by local rather than central government, or that local authorities should levy a sales tax. All this and much more becomes credible once the mass of dead wood hampering the present system has been hacked away.

The relevance to the health services becomes more obvious once one starts to look at the kind of functional and organizational changes which the Royal Commission is likely to consider. Already another committee (like the Royal Commission, under the chairmanship of Sir John Maud) has reported on the "management" of local authorities. It has recommended the abolition of government by departmental committee in favour of a single management committee for determining the main lines of policy in all fields, to be advised by specialist committees. Once this was achieved (and it could take place with or without any structural changes in the authorities as a whole) the traditional career structure of the "professional" local government officers within specialist departments would become less rigid. For, though specialists would still be greatly needed, they would not need to be organized to fit the particular group of jobs allotted to a policy committee, but could be more sensibly grouped according to functions or skills.

Seebohm Committee

As an example of this—and one which directly affects the health services—yet another committee (the Seebohm Committee) is currently considering the future of the local authority "personal and allied services." It is likely to recommend that social workers, whose skills are in demand in many different fields but whose clients may often be the same people with different "problems," should form a separate social work department within the local authority, servicing other departments where necessary. Once this possibility is admitted there is no particular reason why hospital social workers should not also be part of the same or a related organization.

Similarly, housing is a subject which at present involves several different departments: the housing department itself, and the departments dealing with health, architecture, and planning. Yet no one could seriously claim that public health, in the Victorian sense, any longer has a major role in deciding which house should be demolished. Far better concentrate the whole process of building and redevelopment in a single department, which should probably be part of the first-tier authority (there is a good case for making the allocation and management of housing into a second-tier function).

In the course of reorganization, therefore, it looks as if the medical officer of health could lose his responsibility both for housing and for social workers, including the entire welfare set-up. Why indeed should the few remaining traditional responsibilities of the medical officer of health—midwives, health visitors, and a hodge-podge of sanitary and statistical responsibilities—remain as they are? If the health department as we know it disappeared the way would be open for a much more realistic allocation of professional, technical, and administrative responsibility in the health and allied services as a whole.

Area Health Boards

Radical reorganization is no new idea. Back in 1962 the committee appointed by the medical profession to review the medical services (the Porritt Committee)[1] strongly recommended unified control of the three branches of the health service. They proposed that the existing structure should be replaced by area health boards, to which all doctors and health employees should be contracted. Subsidiary professional committees, they suggested, should be responsible for general medical services, for hospitals, and for preventive and social health services. They envisaged that the only bodies that would remain outside (though linked to) the system would be the teaching hospitals. But, because no new health role was suggested for the local authority itself, the committee had to propose a rather awkward solution for the medical officer of health. He should, they said, become the head of a hospital department of social health staffed by health visitors, social workers, and midwives, and be responsible to the area health board. Nevertheless, he should remain responsible to the local authority for "environmental health and hygiene."

There was a great deal of sense in these proposals, but one noticeable omission. Rightly anxious to free the area health services from petty Whitehall interference, nothing in the way of democratic control was proposed to take its place, other than a vague reference to "capable and public-spirited individuals" on the area health boards. Inevitably the impression was given of a system proposed by doctors for doctors. Yet there can be no doubt that health is properly a subject of both local and national democracy. For one thing, a great many decisions concern a choice of public investment—should not a community have a say in whether to build a health centre or provide more kidney machines? Or whether to build more houses, or to provide more maternity beds for people living in poor conditions? An elected body may respond much more readily than a hospital or an independent board to demands from the community itself—for instance, local government has on the whole been much readier than the hospital service to provide child guidance clinics.

It should not in fact be difficult to fit a unified health service directly into the reformed local government structure, substituting for the vaguely autonomous area health boards of the Porritt proposals direct control by the local authorities themselves. The likelihood of a two- (or even three-) tier structure of local government should make this easier—for instance, the major hospitals (including the teaching hospitals, since there is no good reason to exclude them) could be controlled by regional units of local government instead of by the present regional hospital boards. Small local hospitals might fit better into the second-tier functions of local government. At all levels community and medical services could be better linked—thus general practice could suitably become a branch of the lower-tier authorities, the basic unit for all the personal health and welfare services. Public investment could be channelled into group practices, health centres, or Porritt-type departments of social health in hospitals according to the needs of the areas concerned.

More scope could be given to professional administrators to obtain top jobs in the community health services for which the medical profession is not necessarily more suited than any other. Much more scope could be given to doctors, particularly general practitioners, to develop new forms of community care with the full backing of the local authority's hospitals, social workers, and elected representatives. Whether there would still be anybody called the medical officer of health, or what his status would be, matters very little. What does matter is that the system should give doctors every opportunity to develop all branches of the health services in response to real needs, as well as developing the means of finding out what those needs may be. Local government reform could surely provide the opportunity for a better distribution of resources and better support to doctors and their patients.

CONFERENCES AND MEETINGS

Thoracic Medicine

[FROM A SPECIAL CORRESPONDENT]

A conference on various aspects of thoracic medicine was held at the Royal College of Physicians of London on 15 and 16 June. At the first session—under the chairmanship of Professor R. R. A. COOMBS, F.R.S. (University of Cambridge), and devoted to immunology—Professor J. G. SCADDING (Institute of Diseases of the Chest, London) reviewed the conditions in which antigen-antibody reactions were concerned. Classifying the four known types of hypersensitivity reaction, he said that only two of these were commonly associated with bronchopulmonary disease. Type I, the anaphylactic type with immediate weal and flare reactions, was a familial tendency seen in such conditions as hay-fever, perennial vasomotor rhinitis, and infantile eczema. Type III reactions were of the delayed, Arthus type present in farmer's lung. The other forms of hypersensitivity—the cytolytic or cytotoxic Type II—seen in haemolytic anaemia—and the tuberculin Type IV were of less importance in chest disease.

Professor Scadding went on to describe some of the features of aspergillosis—in which allergy to aspergillus infection caused asthma—and farmer's lung, which was an alveolitis due to inhalation of the spores of thermophilic actinomyces released from mouldy hay. There were similarities between the changes seen in the extrinsic asthma of aspergillosis and the alveolitis of farmer's lung which suggested a parallel with intrinsic asthma and cryptogenetic fibrosing alveolitis, and provided a line for future research, since some as yet unknown type of reaction might underlie the latter conditions.

Inhaled Organic Antigens

Concentrating on hypersensitivity to inhaled organic antigens, Dr. J. PEPYS (Brompton Hospital, London) said that Type I hypersensitivity reactions took place in atopic persons, who made up about 10% of the population. They had a constitutional predisposition to sensitization by ordinary, everyday substances, to which they produced reactions of rapid onset and short duration. Delayed hypersensitivity reactions of Type III were seen mainly among non-atopic individuals sensitized by intensive exposure. These reactions were slower in onset, more tissue-damaging, and more prolonged than those of Type I. Inhalation tests had shown that extrinsic asthma could be of either type alone, or mixed. Allergic alveolitis was of Type III and included a number of conditions resembling farmer's lung. These were all caused by fine organic dusts with particles small enough (about 1 μ diameter), to lodge in the alveoli—and included bagassosis, mushroom picker's lung, wheat weevil disease, bird fancier's lung, pituitary snuff-taker's lung, and suberosis caused by inhalation of cork or oak bark dust.

Dr. Pepys concluded by emphasizing that treatment for allergic conditions should always be directed to the patient as a whole and not confined to the immunological findings.

Describing recent work on autoallergic aspects of respiratory disease, Dr. MARGARET TURNER-WARWICK (Elizabeth Garrett Anderson Hospital, London) outlined studies which had demonstrated pulmonary autoimmune reactions of several distinct types. There was, as yet, no direct evidence of a causal connexion between autoantibodies and pulmonary disease.

Surveying the part played by immune reactions in coal-workers' pneumoconiosis, Dr. J. C. WAGNER (Llandough Hospital, Penarth) said that 1% of all coal miners still developed pneumoconiosis, while in Wales the figure was 4%. Evidence for an immunological factor in the aetiology was provided by the presence of a raised titre of rheumatoid factor in many patients with complicated pneumoconiosis. Thus the rheumatoid factor was found in the serum of only 7 out of 35 patients with simple pneumoconiosis, compared with 8 out of 10 with the Caplan type and 10 out of 15 with progressive massive fibrosis and vasculitis; there was often no joint disease in the patients with a raised titre. In the discussion Professor Coombs pointed out that nobody yet knew whether the rheumatoid factor played any part in the pathogenesis of rheumatoid arthritis.

Immunity-deficiency Syndromes

Dr. J. F. SOOTHILL (Hospital for Sick Children, London) discussed immunity-deficiency syndromes, which included functional and quantitative deficiencies in both humoral and cellular immunity. Thus circulating antibodies could be immunologically deficient, though present in normal quantities, or reduced in quantity—as in hypogammaglobulinaemia. Similarly, cellular immunity was deficient functionally in sarcoidosis and quantitatively in lymphopenia. Cellular immunity tended to be neglected because—compared with antibodies—it was hard to measure. Primary antibody deficiency occurred in several familial forms and in the "acquired congenital" hypogammaglobulinaemia of congenital rubella, while secondary deficiencies ranged from physiological low levels in infancy and childhood, to myelomatosis and toxic effects of drugs or neoplasia. As a method of clinical testing, electrophoresis was being superseded by direct immunological studies.

Surgical and medical aspects of scoliosis were the subject of the first morning session, at which Sir HERBERT SEDDON (Royal National Orthopaedic Hospital, London) took the chair. Mr. C. W. S. F. MANNING (Royal National Orthopaedic Hospital) classified scoliosis as postural—which tended to straighten on bending forward—and structural—in which there was fixed rotation and little alteration on bending. Progressive scoliosis was of the structural type and became more severe during growth, especially in early adolescence. Though vertebral, neuromuscular, and thoracic causes accounted for 44% of cases of structural scoliosis, the aetiology was unknown in 56% of 2,000 patients included in a survey, and over two-thirds of these "idiopathic" cases had been adolescents of 11 or over. Treatment consisted of support in a plaster cast or Milwaukee brace, designed to extend the spine without restricting the chest, or operation for spinal fusion.

Effects of Scoliosis

Turning to the medical effects of scoliosis, Dr. P. A. ZORAB (Brompton Hospital) said that breathlessness was associated with peripheral lung deficiency in addition to mechanical causes. Reduction in pulmonary vascular marking noted radiographically was most severe in congenital cases, and post-mortem pulmonary angiograms had demonstrated a definite reduction in peripheral vascularity. There were wide variations in exercise potential. Severe scoliosis could be compatible with full exertion, while mild scoliosis might be associated with severe dyspnoea and disability. On the other hand, pregnant patients generally had normal deliveries even if respiration was impaired.

Continuing, Dr. Zorab said that scoliosis did not cause heart murmurs and had little effect on the electrocardiograph, since the heart's electrical axis was not much changed. Cardiorespiratory failure in middle-aged scoliosis was best treated in much the same way as emphysema—with bronchodilators, antibiotics, and drugs which acted on the heart.

Virus Infections

At the second morning session the chairman, Sir CHRISTOPHER ANDREWES, F.R.S., introduced Dr. D. A. J. TYRRELL (Common Cold Research Unit, Salisbury), who outlined the types of virus known to cause respiratory infection in man. Many of these were very selective in their choice of host cells, and their study had been simplified by the introduction of respiratory epithelium tissue cultures obtained from man or apes. Dr. Tyrrell went on to classify respiratory viruses. The myxovirus group included the viruses of influenza, causing mainly influenza, bronchitis, and bronchopneumonia; parainfluenza 1 and 2, causing bronchiolitis; and parainfluenza 3 and the respiratory syncytial virus, which were both responsible for infections at each end of the age spectrum—bronchiolitis and bronchopneumonia—and also for colds.

Among other types, the rhinovirus caused upper respiratory tract infections, and the Coxsackie and adenoviruses mainly sore throats or feverish colds. By contrast, croup, tracheitis, and sore throats were often due to streptococcal infection. Respiratory viruses could live independently for short periods only and spread most commonly by coughing and sneezing, but hardly at all during speech or normal breathing.

Dr. N. C. **Oswald** (St. Bartholomew's Hospital, London), describing virus infection from the clinician's standpoint, regretted that clinical virology was virtually non-existent. Delays in obtaining a virological diagnosis by culture or immunological methods often meant that the treatment was settled and the patient out of hospital before a result was received from the virus laboratory. Electron microscopy, which could give very rapid results, was useful only for identification of the smallpox virus and the assignment of other viruses to particular groups.

Continuing, Dr. Oswald said that single complement-fixation tests had been performed on 100 consecutive patients admitted to the Brompton Hospital to try to obtain earlier diagnosis of virus infections, but this was only a beginning. More bridges would be needed between hospitals and the laboratory strongholds of the virologists if clinicians were to make intelligent use of antiviral agents when these became available.

Sir **Christopher Andrewes** concluded the session by questioning whether sneezes were necessarily the only means by which respiratory viruses spread. Simultaneous, widespread outbreaks suggested the likelihood of long-term virus latency.

Surface-active Agents

The afternoon session—under the chairmanship of Dr. K. **Robson** (St. George's Hospital, London)—was devoted to surface-active agents in the lungs, and Dr. R. E. **Pattle** (Chemical Defence Experimental Establishment, Porton) described some of the properties of normal alveolar lining fluid, which had a very low surface tension. He demonstrated that lungs in which the surface tension was increased by damage to the alveolar lining collapsed into an airless, liver-like state when deflated.

The importance of low alveolar surface tension in the newborn was emphasized by Dr. L. B. **Strang** (University College Hospital, London). Normal babies needed a pressure of about 18 cm. water for initial inflation of the lungs, followed by much lower pressures for subsequent breaths, whereas the lungs of immature infants required repeated high inflation pressures for each successive breath—because the alveolar surface tension was high and the lungs became airless on expiration. The ability to retain alveolar air and clear alveolar fluid via the lymphatics after birth depended on low surface tension, which probably developed in the human foetus at about 32 weeks.

Describing conditions in which alveolar surface tension was raised, Dr. C. M. **Ogilvie** (Liverpool Royal Infirmary) said that these were of two types: firstly, those in which the mean alveolar size was restricted by shallow respiration of any cause, pulmonary congestion, asthma, or emphysema ; and, secondly, those in which the lining film was abnormal, such as hyaline membrane disease, pulmonary oedema, postoperative atelectasis, respirator syndrome, pulmonary artery occlusion, bilateral vagotomy, and following oxygen or detergent inhalations.

Professor C. H. **Stuart-Harris** (United Sheffield Hospitals) was in the chair at the second afternoon session and introduced Dr. **Lynne Reid** (Brompton Hospital), who emphasized that hypersecretion from the bronchial tree was the fundamental disability in chronic bronchitis. Studies in the rat had shown that it was possible by inhalation of sulphur dioxide under sterile conditions to produce progressive changes closely resembling those of chronic bronchitis, but in which infection played no part.

Further, Dr. Reid had found it possible to compare in the rat carcinogenic with the chronic-bronchitis-inducing effects of inhalation of sulphur dioxide, cigar, or cigarette smoke. All three agents increased the flow of mucus, while cigarette smoke induced numbers of mitoses many times greater than those following inhalation of cigar smoke or sulphur dioxide.

Studies on Chronic Bronchitis

Describing the results obtained so far in prospective studies of chronic bronchitis, Dr. C. M. **Fletcher** (Royal Postgraduate Medical School, London) said that there was now considerable doubt whether infection governed the course of chronic bronchitis, except in the later stages. The most highly significant factors found were the initial level of the forced expiratory volume (F.E.V.)—which was related to the rate of decline—and cigarette smoking. No significant relationship had been found between the course of chronic bronchitis and such factors as episodes of infection, purulence of sputum, or sputum volume.

Though these studies had shown what appeared to be susceptible groups—with low initial F.E.V.—they had left us almost wholly ignorant of the pathogenesis of chronic obstructive bronchitis.

Dr. Fletcher also suggested that in future the histamine-inhalation test might help to distinguish asthmatic from bronchitic patients.

Advances in assisted respiration were the subject of the final session under the chairmanship of Professor Sir **Max Rosenheim**, P.R.C.P. (University College Hospital). The use of controlled oxygen supplements was described by Professor A. **Crampton-Smith** (Radcliffe Infirmary, Oxford) with special reference to intermittent positive-pressure respiration via endotracheal or tracheostomy tubes in the treatment of 52 patients with obstructive lung disease. A small group of patients in status asthmaticus had responded well without tracheostomy and with no deaths ; twenty-four hours of intermittent positive-pressure respiration was usually sufficient if treatment was started early enough.

Among patients with exacerbations of bronchitis, tracheostomy had been performed at twenty-four hours if continued positive-pressure respiration was necessary. There were twelve deaths—all in this group. Dr. J. M. K. **Spalding** (Radcliffe Infirmary, Oxford) concluded the meeting by describing the changes in circulation, renal function, and acid-base balance resulting from increased intrathoracic pressure.

TOMORROW'S BUILDINGS

New Teaching Hospital at Oxford

At a press conference in Oxford on 14 June details were announced of the new regional hospital planned for Oxford. The hospital will be built on a 69-acre site south-east of the city centre, part of which is occupied by the Osler and Sunnyside Hospitals. It is intended to serve two main functions—firstly, that of a community hospital, and, secondly, that of a major centre for medical research providing comprehensive teaching facilities at both undergraduate and postgraduate level.

Building on Phase I of the hospital is planned to start early next year. This will comprise a 167-bed maternity unit, the Nuffield Institute (a research laboratory), and residential accommodation for 147 staff. The maternity unit will be on seven floors, with an acute floor (including admission and delivery suites ; operating-theatres ; special nursing, medical care, and baby care units ; and the University Department of Neonatal Medicine) at ground level. The third floor will house the University Department of Obstetrics, while on the fourth, fifth, and sixth floors there will be wards containing a total of 141 beds. The seventh floor will house a 10-bed isolation unit with its delivery room together with a 10-bed private patients' unit.

It is hoped that building on the next stage of the development—Phase 2A—will start immediately after Phase I has been completed, possibly in 1971. This will contain a new accident and emergency department, beds for 450 patients, a new children's ward, and further residential accommodation. The University Grants Committee has approved the provision of a large research building to support the various clinical departments. In addition, there will also be a new headquarters for the undergraduate medical school with a central medical library, lecture theatres, and seminar rooms, and a demonstration hall. In this way it is intended to create an academic centre open to students, teachers, general practitioners, and local-health-authority staff alike.

The consultant architects for the new hospital are Yorke Rosenberg and Mardall.

WITHOUT PREJUDICE

I should like to begin this page once more with Mr. Desmond Donnelly's contribution to the debate in the House of Commons on 9 June, the debate in which other Labour M.P.s also had the courage to challenge outmoded concepts of running the N.H.S. "At root," Mr. Donnelly said, "what I am concerned about is the humanity of the State towards the individual. What I am representing, really, is a radical reaction on behalf of the individual against the State." That declaration of faith brings him straight into my political category of "progressive reactionary." He reacts and wants to progress.

Mr. Donnelly was concerned with the size of the human unit for doing certain jobs. We have moved, he said, from the city State to the nation State, and are now moving to the super-State. A nation of 50 million people is too small for certain purposes of defence and commerce. At least that is the argument. And now the super-State is, or is supposed to be, under the governance of the World State or United Nations. All this dwarfs the individual. He feels desperately insecure and frightened. The size of the machine and its omnipresence make the individual doubt even his own identity.

It is when the State descends to the particulars of a case that the individual feels deprived of his stature as an adult. It is at this point that doctor and patient both suffer when subject to remote decision and control. The nation State is the right unit for managing certain movements of health and disease. It must have an overall plan. It has to protect the ports and frontiers from invasion by germs. But it attempts to do too much when it tries to direct the work of the individual doctor or prescribe too closely the way of life of the individual patient.

* * *

The machine of Government gets clogged with the small bits and pieces of social and political life. This is worrying many people. "The only way," Mr. Donnelly said, "in which we can get this logjam of decision-taking broken up is by devolving from this House a large number of matters which come before it now." He called for wider groupings of local authorities: "We have to devolve a large number of what one might call the incidence of government to regional, elected authorities or parliaments." Mr. James Griffiths would hand over some of the planning functions to elected regional councils and entrust them with the administration of the hospital service.

I fear, however, that as a nation we may have reached the stage of administrative rigidity which makes radical reform or adaptation to new conditions impossible. As Mr. Donnelly puts it, even when administrators themselves admit the need for reform, "change can be prevented by bureaucratic complexity and by the disorientation of motive and lack of adaptability and initiative among the very class of men necessary to implement that change."

It seems, from a statement by the Government spokesman, Mr. Niall MacDermot, that the Government is likely to favour less radical proposals than those put forward. The general conception, according to him, "is that one would get a region comprising what at the moment would be one county, or perhaps two, and a city which would be a centre to that region. It would be a transformation of the present county level, I think, with one other level of local government below it." But he doubted whether this kind of change would speed up the making of decisions or result in any reduction in the size of the public service. It depended on whether a great deal of the power to make decisions was going to be transferred to a lower level. "This is where the crux of the problem arises as to what are the functions that one envisages should be devolved."

I hope that the Government will not be long in staging a full-scale debate on the matters brought to the surface on 9 June. As Mr. Houghton said then, "we have probably provided the agenda for another occasion." The worst possible thing that could happen is the slow and almost imperceptible deterioration of the N.H.S. accompanied by the silent but continuous protest shown by the rising figure for emigration.

* * *

I look forward to the first Henry Miller report, and hope he will beat the politicians to the post. But he won't if he thinks he is going to get another £500 million out of taxation. As Mr. Donnelly said in the Commons debate in reference to this, "If there is any honourable Member who knows how we can raise £500 million next year for this purpose let him stand up. It cannot be done." But I feel sure that with substantial devolution of power and responsibility—the two must go together—to the periphery local efforts to raise money will succeed. Region South-west will be determined to show a thing or two to Region South-centre. Local people will be eager to raise extra funds for *their* hospitals, for *their* kidney centre, for *their* health clinics. Their enthusiasm might even carry them to the extreme of being willing to pay for their ordinary drugs and even to spare the odd obol for their ordinary doctors. They must have a focus for pride and enthusiasm.

* * *

Support for devolution comes from quite a different quarter, I am delighted to see, in the article by the distinguished economist Colin Clark in his contribution to the *B.M.J.* on 27 May. "What I do want to say, as emphatically as possible," he said, "is that if there have to be public authorities providing medical service they should be local or regional, not national. There are strong objections to unduly large-scale organizations, in this as in other fields." But he is equally emphatic in his view that there will be genuine devolution of responsibility for running hospital and medical services only if the regional authorities spend their own funds raised from taxes or fees from the inhabitants in the region.

In this matter he too, like Mr. Donnelly, is concerned with the optimum size of an organization. How large is too large? He quotes Professor Florence as saying that "no man ought to be required to be responsible for supervising in the direct line of command more than five subordinates. . . ." Another authority has said that when the principal officials of an organization spend more time in committees than in getting on with their jobs the organization is too big. And Colin Clark quotes an eminent civil servant thus: "The bigger an organization grows the more readily it falls a victim to the disease of bigness—indecision, apathy, routine and red tape, personal intrigue, confusion of counsel and responsibility . . . duplication of effort, waste of time in establishing responsibility, elaborate consultation, petty sabotage." We have been warned.

Mammoth organizations and Government departments will go the way of all mammoths and plesiosaurs and such-like creatures if they overgrow their strength and therefore capacity to survive. As Colin Clark observes, it has all happened before. And he joins with Desmond Donnelly in pointing a warning finger to ancient Rome in the period of her decline and fall.

All this has to do with the health of the ordinary citizen and his relation with the hospitals in his neighbourhood and with the doctors and nurses and other health workers. The N.H.S. will have to be moulded afresh with the help of new minds determined to give it a secure local habitation within the national framework.

Or are we just to sit passively and watch the progressive decline of Britain as if it was a show on the television screen?

Casualty Department—or G.P. Service?

SIR,—A survey of patients was undertaken at this hospital to determine the way the casualty department was used. Each year about 11,500 new patients are seen, and there is a total attendance of 25,000. Eighty per cent. of the new patients and all re-attendances are seen by the casualty officers between the hours of 9 a.m. and 9 p.m. The remainder of the new patients presenting during the night are seen by the resident house-officers.

An analysis of all new patients attending over the three-month period from October 1966 to January 1967 was made. They were divided into four main groups.[1]

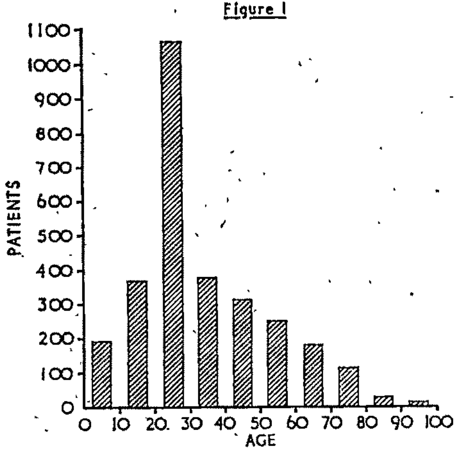
(1) Accidents.
(2) Medical emergencies.
(3) Surgical emergencies.
(4) Casual attenders.

All were then considered in relation to age. The reason why patients in Group 4, the casual attenders, came to hospital was also examined.[1-4] The survey was completed by correlating the cases with the population and type of area which the hospital serves.

Accident cases account for 52% of the patients seen, medical emergencies 9%, surgical emergencies 11%, and casual attenders 28%. These figures represent the average for all age groups, but there was no marked variation when each decade was considered separately.

A most striking feature which emerged was that nearly 40% of all new patients attending the department were between 20 and 29 years (Fig. 1).

Figure 1



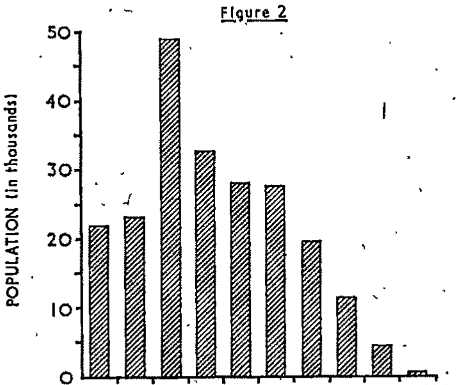
The reasons given by casual attenders for their call on the hospital service were:

(1) The patient had no general practitioner in this area—37%.
(2) It was more convenient to come to the hospital than to see or call their own doctor—27%.
(3) The patient's own doctor had no surgery that day or was not available—15%.
(4) Patient was a visitor to London—8%.
(5) The patient was under the care of the hospital for some complaint and therefore felt he or she should always be seen at the hospital—7%.
(6) The patient wanted a second opinion—6%.

The hospital serves mainly the Kensington and Chelsea districts—that is, the following London regions, W.8, S.W.5, S.W.7, and part of W.14. It is a densely populated area with heavy urban traffic, many hotels, but very little industry. All social classes are represented; there is a high student population and many young people living in "bed-sitters" and flats.

The number of young patients attending the casualty department is high, and this is probably typical of most casualty and accident departments.[1,3,5] It also conforms to the age distribution of the local population (Fig. 2).

Figure 2



There is a high percentage of casual attenders, but the department is still called "casualty" rather than an "accident and emergency department." We feel that a change to the latter would not cause a significant drop in the number of casual attenders because:

(1) A certain number of people will always present themselves at a hospital demanding attention.
(2) Type of area served: the department sees visitors to London if they are taken ill in this area.
(3) The shortage of general practitioners.

This last factor seems significant. Nearly 40% of the casual attenders are not registered with a general practitioner in this locality, and of these nearly a quarter had tried to register with one or more doctors before seeking the aid of the casualty department. We assume that if the other three-quarters of the casual attenders with no local doctor attempted to register they would meet with the same problem. Of our casual attenders 10% are registered with a practitioner in another area. About 25% of all our patients resident in this area (as opposed to visitors and those in transit) have no local general practitioner. It has been stated that there is no need for hospitals to provide a general-practitioner service.[2,5] Our experience suggests that if this hospital did not maintain its "open door" policy many people in this locality who required medical attention would receive none.—We are, etc.,

Endotracheal Tubes

SIR,—Reviewing the changing pattern of anaesthesia in a general hospital, Professor W. W. Mushin and his colleagues note that the greatest number of operations in any one year of life occurred in children up to 1 year.[1] It is probable that there is an increased use of endotracheal anaesthesia in infancy.

In 1962 experts from the Admiralty, War Office, Air Ministry, and others assisted the British Standards Institution to draw up a specification for endotracheal tubes.[2] Tubes to this standard are now marked according to the internal diameter. They are available from 2.5 mm. to 11 mm. in 0.5-mm. steps with an allowed tolerance of ±0.2 mm. The thickness of the wall in the first five tubes is identical—namely, 0.6 mm., with a tolerance of +0.2 mm. or −0.1 mm. A 4.5-mm. tube has a wall thickness of 0.6 mm., but a 5.5-mm. tube has a wall twice as thick—1.2 mm. Thus what at first sight appears to be an even grading results in considerable differences in external diameters. Also the limits of tolerance allowed the manufacturers permits quite a large variation.

The area of the air passage at the level of the cricoid ring of the newborn is approximately 14 sq. mm.,[2] and 1 mm. of oedema will reduce this area by 65%.[3] Familiarity with the Hagen-Poiseuille law may tempt junior anaesthetists to use too large a tube for an infant, especially if relying on a formula to calculate the correct size. If tubes were available with a more even progression in their external diameters this law might be more safely and less traumatically applied.—I am, etc.,

Heavy Uterine Bleeding

SIR,—In reply to a question (20 May, p. 494) your expert says that for practical purposes the only haemorrhagic disease associated with heavy uterine bleeding as a direct effect of the disease is idiopathic thrombocytopenic purpura. It is certainly the most important disease in this respect, but I think there are others which, although they are rare, should be remembered.

Buxton,[1] in reviewing 108 cases of purpura haemorrhagica, aplastic anaemia, and leukaemia, showed that in no fewer than 10 of these patients the initial and chief complaint was menorrhagia, and they were first seen at a gynaecological clinic. Hysterectomy was performed on one of them. The uterus revealed no pathology, and the patient died from aplastic anaemia. A second case of aplastic anaemia and a third of acute lymphatic leukaemia were likewise fatal. The other seven cases were of purpura haemorrhagica. Wheaton[2] reported three cases of leukaemia which presented as gynaecological emergencies. I have seen three fatal cases in which heavy uterine bleeding was the first sign of a blood disease. All three were admitted as gynaecological emergencies. One was a case of subacute lymphatic leukaemia and the other two were examples of agranulocytosis due to toxic drugs.

In my opinion abnormal uterine bleeding may be an important symptom of the following diseases of the blood: aplastic anaemia; agranulocytosis; the leukaemias; the purpuras; splenic anaemia; and secondary thrombocytopenia due to *x* rays or toxic drugs.—I am, etc.,

Prevention of Rh Haemolytic Disease

SIR,—Recent reports[1-4] have demonstrated clearly the value of anti-D gammaglobulin in preventing the stimulation of Rhesus (D) antibodies by transplacental leakage of foetal red cells. Because of the shortage of anti-D gammaglobulin much attention has been devoted to the dose necessary to provide protection in routine use. As none of the series yet published has been able to include a case of massive transplacental haemorrhage so treated, the following case may be of interest.

A 21-year-old primigravida, blood group A Rh (D) negative with no antibodies detectable in the 34th week of pregnancy, was admitted in labour at 41 weeks to Portwey Hospital under the care of Mr. S. H. Riterband in September 1966. After a labour lasting 54½ hours, assisted breech delivery of a living male child weighing 8 lb. 5 oz. (3.78 kg.) took place. The condition of the infant initially appeared satisfactory but later deteriorated, and after 24 hours he was noted to be extremely pale. Haemoglobin was 8 g./100 ml., blood group A Rh (D) positive, direct Coombs test negative, serum not icteric. Examination of maternal blood at this stage revealed by the acid elution test[5] that a massive transplacental haemorrhage had occurred. Approximately 3,400 foetal cells were present in 50 low-power fields; equivalent to about 170 ml. of foetal blood. Precisely when the haemorrhage took place is not clear, but examination of the foetal heart record indicates that it was not more than twelve hours before delivery.

Anti-D gammaglobulin (5 ml.) was very kindly supplied by the Department of Medicine, University of Liverpool. The strength of this preparation was probably of the order of 700 μg./ml.[6] Owing to delay in diagnosis and transport difficulties the time interval between delivery and intramuscular administration of the gammaglobulin was just over 72 hours. The injection evoked no reaction in the patient.

Thirty-six hours after the injection the volume of foetal blood in the maternal circulation was reduced to about 80 ml., and these remaining cells gave a positive direct Coombs test. Free antibody was demonstrable in the serum at a titre of 1 in 4 by indirect Coombs test against R_1R_2 cells. On the tenth day after gammaglobulin less than 0.25 ml. of foetal blood was present and free antibody was still detectable to a titre of 1 in 4.

At three months and seven months after delivery maternal blood was examined for the presence of immune anti-D. None was detectable by saline, albumin, enzyme, or indirect Coombs techniques.

Whether the blocking of antigen sites on the foetal cells or the presence of free antibody is the determining factor, this case demonstrates that 5 ml. of anti-D gammaglobulin is sufficient on both counts against a foeto-maternal transfusion equivalent to more than half the blood volume of the baby. Absence of immune antibody, though not constituting absolute proof, suggests that immunization may have been prevented and that the proposed dose of 1 ml. for use in the cases more commonly found may well be sufficient.

I am indebted to numerous people, in particular to Professor C. A. Clarke, for assistance and to Mr. S. H. Riterband for permission to publish this case.

Unusual Bone Abnormality in Congenital Rubella

SIR,—The radiographic changes in the skeleton which are considered to be pathognomonic of congenital rubella have been described in detail by Rudolph *et al.* and Singleton *et al.*[1-3] Briefly, these consist of poor mineralization with irregularity of the growth plate and altered trabecular pattern in the metaphyses of long bones. The distal ends of the femora are particularly affected. These usually heal spontaneously. Retardation of knee ossification centres also occurs. These bony abnormalities are more likely to occur in infants with multiple rubella defects. The lack of periosteal reaction has been stressed. Recently, Peters and Davis[4] have reported details of an infant with the congenital rubella syndrome in whom there was considerable periosteal new bone formation in several long bones, together with the usual features of rubella osteopathy. The infant had thrombocytopenic purpura and they postulated that the changes were the late results of subperiosteal haemorrhages.

An unusual bone lesion has recently been observed in a male infant with congenital rubella. The mother had rubella four weeks after her last menstrual period. The infant had bilateral cataracts and suffered from unexplained heart failure in early life. Rubella virus was recovered from the nasopharynx and the urine on admission at 3 weeks of age, and on several occasions up to 8 months. Platelet counts were normal. Psychomotor development at 12 months of age was delayed.

At 3 weeks of age a skeletal study showed mild but typical metaphysial lesions in the tibia and femora, and delayed development of the distal femoral and proximal tibial epiphyses. There was poor mineralization of the skull with ill-defined suture margins, but some irregular thickening was present in the frontal region. In the right clavicle an area of rarefaction was present towards the lateral end of the bone and lying centrally within it. In the next three months this lesion expanded and sclerosis and thickening due to periosteal new bone formation developed medially. At 7 months the medial and middle thirds of the bone were thickened but the lesion had not expanded further. At 1 year the right clavicle was of normal shape and structure.

This unusual clavicular lesion could represent a true osteitis due to rubella. Maternal rubella is known to have occurred in this case 28 days after the last menstrual period; thus foetal infection occurred at a very early stage in development. It is noteworthy that the clavicle is the first bone in the foetus to ossify. Ossification proceeds initially from two centres developing at about 5–6 weeks of intrauterine life. The time of the intrauterine infection may explain the localization and nature of the lesion in this case.—We are, etc.,

West Indian "Stomach"

SIR,—I was most interested to read Dr. K. A. Taylor's letter headed "West Indian Stomach" (3 June, p. 641). However, I was surprised that he did not find more conditions related to the chest.

I have recently returned from a spell of general practice in the West Indies, and when a patient complained of his "stomach" this usually referred to the chest or anything between the neck and epigastrium. The abdomen was usually referred to as the belly, and a fairly common presenting symptom would be "a cuttin' in the belly," "a cuttin'" meaning pain. The commonest complaint was of the "bad feels" and it was often very difficult to get any further than this. The word discharge did not seem to be used in any form and to ask if there was a vaginal discharge was of no avail, this being always referred to as "inflammation." One thing I did find most curious was that although the word " period " was not used, menses was clearly understood (and was an everyday word), although women were usually rather coy of mentioning having missed them and that they might be pregnant. It was often rewarding because of this to question any woman in her reproductive years about her menses if she came along with some other rather trivial complaint.

Hypertension was common to an extent that I often found myself considering whether the English idea of normality ought to apply. Strokes were common, a stroke being referred to as a " passover," but interestingly enough hypertensive left ventricular failure was infrequent, possibly because their coronary arteries are better able to deal with the muscular hypertrophy. It might be of interest to note here, for those interested in the aetiology of coronary artery disease, that although the sugar content of the diet was high (a sugar-producing country) there seemed to be very few cases of coronary artery disease in the practice. A common complaint was of " a beatin' in the head " and this was invariably associated with concern regarding their blood pressure, and it was always expected of the doctor to check their blood pressure if they came with this complaint. Often it was normal and they could go away happily reassured.

With further reference to the anatomy I found it helped a great deal when I learnt from my seniors that a complaint regarding the foot could apply to any part between the toes and the buttock, and a complaint regarding the hand to any part between the fingers and the shoulder; up till then I had found it a little confusing when the patient placed his hand on his hip and referred to a pain in the foot.

I must make it clear that the coloured section of the practice was principally drawn from agricultural workers on the sugar plantations together with a smattering from other occupations (hotels, etc.) and the observations I have made deal solely with my experience in this practice. The work was practical, interesting, and variable and if private general practice could be associated with a free national pharmaceutical service as well as a free hospital service it would seem to me the ideal way to practise medicine. Poverty was no barrier to proper medical care, abuse particularly with regard to visits was minimal, and the frivolous use of one's time was at a premium which the patient both expected and accepted.—I am, etc.,

London E.2.

Pericarditis in the Tropics

SIR,—Dr. K. Somers's article " Pericarditis " (13 May, p. 423) makes many statements with which I agree entirely, but the following exception prompts me to write, lest a useful drug be discarded by some of your readers. Saying that " emetine usually has no effect on hepatic amoebiasis " is as far from the truth as making the same statement about penicillin G and beta-haemolytic streptococci. On occasion one may find chloroquine to be more effective in a specific case than emetine, but just as often the opposite may be found. The advantages of an oral versus an intramuscular medication should not be overemphasized when the patient is ill enough to be in hospital. The toxicity of both drugs makes it valuable to be able to choose between the two and not be forced to use only one.

Emetine has been effective for the treatment of hepatic amoebiasis since first reported by Rogers,[1] and it continues to be a most useful and life-saving drug. Our experience[2] would make us think that the batch of the alkaloid used by Dr. Somers must have come from an unreliable source before we would consider that the Ugandese variety of *Entamoeba histolytica* is emetine-resistant.—I am, etc.,

Infant-scalp Vein Needles

SIR,—Dr. C. F. P. Wharton's description about the use of infant-scalp vein needles (10 June, p. 702) has been quite interesting. I describe here a further use that these can be put to in adults, best illustrated by a brief case history:

> A 29-year-old man with acute fulminating ulcerative colitis had to have four operations in a period of three months. Repeated blood transfusions, continuous intravenous feeding, checks on haemoglobin, blood urea, electrolytes, etc., together with an extreme degree of wasting, had led to the blockage of almost all his superficial venous channels by thrombosis. These felt like thick cords under his skin. Nearing the end of his last operation for removal of the terminal colon and rectum his intravenous infusion stopped and intravenous cannulation became impossible. As the patient was slightly shocked, immediate cut-downs were made, first on both his cephalics, and then his saphenous, only to reveal thick cords without any lumen.
>
> In desperation a scalp vein needle was inserted into a small peripheral vein on the right wrist. To our surprise, in spite of all his superficial veins being blocked proximally, the flow through this was rapid and adequate, and 2 pints (1,080 ml.) of blood and 1 pint (540 ml.) of plasma could easily be pumped through this with the aid of a Martin's pump. Intravenous infusion was continued through the same needle for four days postoperatively, when it finally stopped. A similar one was put into a small vein on the other side and continued for a further four days.

Thus it seems that an infant-scalp vein needle can be used in shocked adults with collapsed veins where it may be difficult to get into a vein with a Branula, Intracath, or an ordinary " giving " set needle, especially when a cut-down has failed, as contrary to expectation one can easily pump blood, plasma, or fluid through it at great speed.—I am, etc.,

Cephaloridine in Acute Pulmonary Infections

SIR,—Dr. P. Howard (27 May, p. 573) states that cephaloridine in a dose of 6 or 8 g. daily might be very effective in bronchial infections. This has been confirmed in a controlled trial in patients with severe and resistant, chronic, purulent bronchial infections.[1] Cephaloridine was compared in doses of 2, 4, and 6 g. daily to penicillin 6,000,000 units with streptomycin 1 g. daily. With the 2 g. dose of cephaloridine, penicillin and streptomycin was significantly more effective, with the 4 g. dose equal in effect, and with 6 g. definitely inferior both in short- and long-term clinical and sputum assessment. Unfortunately 6 g. daily of cephaloridine is associated with massive outpouring of hyaline casts.[2] Although this cast excretion is of uncertain and doubtful significance, 6 g. of cephaloridine daily should be given only when other antibiotics have failed and/or where the patient is very ill.—I am, etc.,

Banning of Heroin

SIR,—May I point out that the manufacture and distribution of heroin has been banned in Australia for a number of years (1 April, p. 53). This does not seem to have hindered the illegal trafficking of this drug, but merely to have pushed up the price on the black market. After using heroin in practice in England for a number of years I find its prohibition in Australia irksome to me, and an unnecessary injustice to an unfortunate few of my patients.

A letter on this subject published in the *Medical Journal of Australia* recently[1] produced no response at all from fellow practitioners. The greatest tragedy of this ban seems to be that we have a generation of doctors here that is unaware of the merits of this drug, but only the dangers they read of in the Sunday papers.—I am, etc.,

B. HEBER.

Drug Addiction

SIR,—In your leading article on " Drug Treatment Centres " (20 May, p. 455) you point out that we know little yet of the ecology of the different types of drug addiction, or of the social factors which encourage or precipitate it. While drug addiction is fortunately quite rare, a taste for pop music is almost universal among young people and pop singers are acknowledged leaders of fashion. It is therefore an alarming development that the worlds of pop and drugs are becoming more and more closely identified in peoples' minds. Not only are there widely publicized pronouncements by entertainment personalities regarding narcotics, but many popular lyrics carry thinly veiled references to drug-taking and the word "psychedelic," with all its associations, is freely used in press reviews of pop records.

Surely the image projected by popular entertainers is a powerful social factor which favours drug-taking.—I am, etc.,

J. TWOMEY.

Tremulous Iris

SIR,—We are interested in the syndromes associated with congenital non-traumatic ectopia lentis. In your recent leading article on tremulous iris (11 March, p. 585) you state that osteogenesis imperfecta has been recorded, accompanied by ectopia lentis, in a patient reported by Behr in 1913,[1] a citation also given by J. H. Stone[2] and V. A. McKusick.[3] This paper in fact described a 38-year-old widow who suffered progressive diminishment of visual acuity from the age of 12. Severe myopia with bilateral microcornea, keratoconus, and blue sclerotics were found on examination two years later. At the age of 19 years her hearing was noted to be poor and she became totally deaf in her early twenties. Her most troublesome complaints were due to recurrent spontaneous dislocations of the large joints; at first the left foot and knee joints and later a dislocation of the left shoulder joint occurred while the patient was "carrying a laundry-bag downstairs." She was observed in the University Eye Clinic in Kiel for 24 years and ectopia lentis was never recorded.

May we add that the title of Behr's paper was most misleading—"Keratoconus, blue sclera and chronic dislocation"?—We are, etc.,

Inflatable Splints

SIR,—Dr. Heather Ashton's article on the danger of inflatable plastic splints (10 December 1966, p. 1427) has been received with disbelief by clinicians in this country who have used it. Controlled experiments by J. B. Spooner and colleagues (4 February, p. 297) showed that the indirect method of recording blood flow described in Dr. Ashton's article was inaccurate because the sensing device itself was subjected to the pressure of the splint. For some reason Dr. Ashton ignored publications dealing with the safety of the principle.

My interest in the clinical application of circumferential pneumatic compression dates back to the second world war, when I began to apply the principle of the aviation G-suit to prevent postural hypotension in patients operated upon in the sitting position.[1] Experience showed that if a wrap-around plastic G-suit was inflated with a patient supine its splinting effect would interfere with placing him in the sitting position. This suggested the idea of an inflatable splint, and an experimental model was developed at the Cleveland Clinic in 1952. In 1958[2] the effectiveness of this principle in controlling bleeding was reported. The manner in which circumferential pneumatic compression stops arterial bleeding without interrupting blood flow was described in 1966.[3-4]

When we first began to investigate the pneumatic splint we also thought it dangerous to employ pressures in excess of capillary pressure.[5] For this reason it was decided to study the problem in the laboratory. We began by employing a pressure we felt certain would cause gangrene in the dog's leg. Because the marked tapering of the hind leg caused the inflated splint to creep downward at high pressures, the foreleg was selected. The pressure in the splint was held at 180–200 mm. Hg for five hours. On recovery from anaesthesia the dog walked normally and with no apparent ill effects. In the next test a pressure of 300 mm. Hg was applied for six and a half hours. This dog exhibited only a wrist drop, which cleared within a week. In the next animal a pressure of 300 mm. Hg was applied continuously for ten hours. After the splint was removed the leg became extremely swollen. The oedema subsided in seven days, but a wrist drop persisted for five weeks. There was no loss of tissue nor other evidence of damage. These results suggest that circumferential pneumatic compression applied to a large area of a limb is safer than when applied to a small area, as by a blood-pressure cuff. Why this should be so is at present being investigated.

Angiographic studies employing time-lapse cinematography were done on the foreleg of a dog whose blood pressure was 170/110. With pressures in the splint above the systolic the flow of Hypaque in the brachial artery appeared to be completely arrested; despite which, within seconds, some of the medium appeared in veins below this level. At a pressure of 120 arterial flow was present during systole. At a pressure of 90 flow was maintained during diastole. These findings, admittedly at variance with the theory of the critical closing pressure of blood vessels, were not mentioned by Dr. Ashton.

Hartman[6] employed the inflatable plastic splint as a dressing after meniscectomy. He applied it from mid-thigh to a point above the ankle at 30 mm. Hg for 48–72 hours. It prevented oedema and effusion, and for some unexplained reason oedema of the protruding portion of the limb did not develop.

Dr. Ashton describes her splint in which two layers are sealed together at intervals to produce longitudinal, inflatable sections. She reaches the conclusion that pressures are applied only to sections of the limb beneath the inflated portions. We tried this principle and found that pressure on the limb under the uninflated strips was greater than that under the inflated portions. This is a demonstration of the law of Laplace. Since Dr. Ashton quotes A. C. Burton, with whom I have been in communication during my studies, obviously she is aware of the law of Laplace.

Dr. Ashton further states that "in all patients tested rhythmic contraction of the forearm muscles after inflation of the splint produced typical ischaemic muscular pain in the forearm after 10 to 20 contractions." This is at variance with some unpublished data from the Cleveland Clinic. A pneumatic splint was applied to the calf in six patients with intermittent claudication. In each case inflation to 30 mm. Hg (by actual measurement) resulted in no reduction in the claudication distance.

Unfortunately, Dr. Ashton's article has now been abstracted in *Modern Medicine*. The further dissemination of this publication is certain to deny to innumerable patients the benefits of this amazingly safe, therapeutic device.—I am, etc.,

W. JAMES GARDNER.

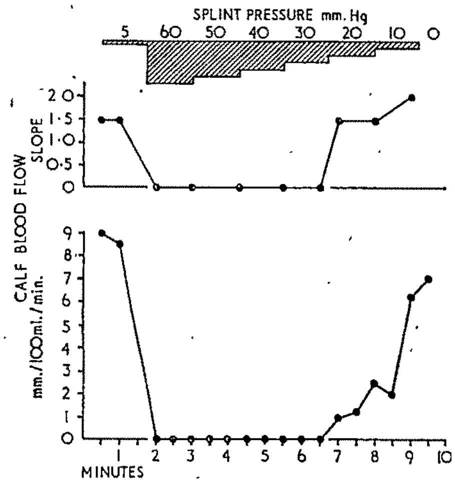
SIR,—I have been interested in the correspondence provoked in your columns by my paper (10 December 1966, p. 1427) in which it was reported that a plastic splint applied to a limb and inflated to a pressure of 30–40 mm. Hg may impair the underlying circulation. I am surprised by Dr. W. J. Gardner's statement above that my findings have been received with disbelief in the U.S.A., since a recent paper by Ginsberg *et al.*[1] from Fort Howard, Maryland, not only confirms my findings but also adds a warning that the effects on the blood flow in the enclosed limb should be taken into account by prospective users of the splint.

Both Dr. Gardner and Drs. J. B. Spooner, S. J. Corne, and R. J. Stephens (4 February, p. 297) are doubtful about the validity of the method used to assess blood flow, because the sensing device was subjected to the pressure of the splint. However, I also showed in my paper (Fig. 3) that the same results were obtained when blood flow was measured distal to a splint and the sensing device was not subjected to the splint pressure.

Moreover, my results are by no means isolated findings peculiar to the method employed. Many workers, using a variety of methods, have shown that the application of an external pressure to a limb or digit causes a reduction and sometimes a complete cessation of blood flow. For example, Burton and Yamada[2] with pressure plethysmography of the forearm, Roddie and Shepherd[3] with heat flow discs on the fingers, and Gaskell and Krisman[4] with microscopic observations of nailbed capillaries, all came to the same conclusion, and their results have been confirmed by other workers. In all these studies an external pressure of 40 mm. Hg was regularly observed to reduce blood flow considerably, and in a proportion of subjects flow was apparently reduced to zero.

In addition, studies with radioactive sodium injected into the calf or forearm muscle show that the clearance of this may cease altogether in some subjects when a splint is inflated around the limb to pressures around 40 mm. Hg (see Fig.). These studies are being carried out with Professor D. N. Walder, Department of Surgery, University of Newcastle upon Tyne. Non-clearance of radioactive sodium from an area of muscle can only mean that there is no blood flow through that area of muscle, and this observation thus supports the other evidence that inflation of a splint can on occasion stop the blood flow, at least through muscle.



Blood flow in the calf of a normal subject under a plastic splint enclosing the foot and leg from above the knee. Splint inflation pressure is indicated at the top of the Figure. Upper trace shows the rate of clearance of radioactive sodium injected into a portion of calf muscle (in arbitrary units representing the slope of disappearance of the isotope). Note that a horizontal slope indicates that there is no clearance. Lower trace shows blood flow in ml./100 ml./min. as measured simultaneously with a mercury-in-rubber strain gauge around the calf.

Thus at least five different methods for assessing blood flow have given results in similar circumstances. All these methods, as Dr. Gardner points out, are indirect, for there is no direct method for measuring blood flow through small vessels, such as arterioles, in intact human limbs subjected to external pressures. But there is direct evidence from microscopic examination of intact mammalian vessels that small vessels can and do suddenly close down when arterial transmural pressure is lowered.[5] A theoretical reason for this has been discussed by Burton,[6] and the presence of a flow cessation pressure in vascular beds,[7] whatever the mechanism by which it is caused, is generally accepted among circulatory physiologists.

Apparently conflicting evidence was reported by Dr. Gardner,[8] who found that in dogs with splints inflated around the forelimb the injection of 10 ml. of a radio-opaque medium into the subclavian artery is followed by visualization of the medium in the brachial artery and subsequently in the veins. He did not state, however, the pressure at which the radio-opaque material was injected. Yet this must have been above the systolic blood pressure, and the injection must therefore temporarily have raised the transmural arterial pressure. This would have the same effect as temporarily lowering the splint pressure and would allow an opening up of small vessels that were previously closed. Therefore his findings cannot be accepted as showing that under normal circumstances an appreciable blood flow continues through small vessels under an inflated splint. The main arteries are known to remain open, as evidenced by the fact that arterial pulsation in the part under the splint is undiminished, and it may be that a trickle of blood, confined to bone or interosseous vessels protected from receiving the full splint pressure, persists.

For similar reasons, the experiments of Drs. Spooner, Corne, and Stephens cannot be considered relevant to the usual situation under a splint, for in assessing blood flow they used a congesting cuff pressure greater than diastolic pressure. As noted by Greenfield[9] "too high a pressure in the collecting cuff may cause it to act as a valve, preventing diastolic reflux, and artificially elevating the mean arterial pressure downstream." Diastolic reflux of blood occurs in a variety of conditions[10] [11] and almost certainly occurs in the present case.[3]

The important practical question, of course, is not whether the blood flow can cease absolutely under a splint but whether a considerable reduction in blood flow might be harmful. Even apart from the evidence already referred to, most observers who have seen the blanched skin under a plastic splint, and the reactive hyperaemia on its removal, agree that the blood flow is at least reduced. My purpose in publishing my results was to warn users of such splints of their possible effect on the circulation. They may not have harmed the normal dogs referred to in Dr. Gardner's letter, but can one be sure, for example, that severe reduction in blood flow does not delay the healing of fractures ? Can one be certain that a tightly inflated splint will not precipitate gangrene in a diabetic with an already impaired peripheral circulation ?

Proper precautions, however, need not detract from the general usefulness of the splint. In some circumstances the reduction in blood flow resulting from splint inflation may be useful *per se*, for instance in controlling haemorrhage.[12] Dr. Welply (4 February, p. 297) also suggests that a reduction in blood flow might sometimes be desirable. Nevertheless, I would maintain that until further information is forthcoming it would be prudent to ensure that splints of the present design are not inflated to pressures exceeding 30 mm. Hg.—I am, etc.,

Frozen Sections

SIR,—Your leading article "Frozen Section in Surgery" (18 March, p. 651) prompts us to remind you of our previous letter to you.[1] We do not agree that frozen section "remains unchallenged in the rapid diagnosis of lesions before their treatment by surgical means.". As reported previously, drill biopsy[2] [3] performed as an outpatient procedure provided a correct diagnosis in 96% of patients with lumps in the breast, and a report of the histology on a paraffin section could be obtained within 24 hours. The advantage of having a histological report in this way is that it enables the surgeon to plan the subsequent treatment with the patient's full knowledge and co-operation. In our experience drill biopsy causes little trauma to the breast and opens up fewer venous and lymphatic channels than does an open biopsy.—We are, etc.,

Colistin in Purulent Bronchial Infections

SIR,—I read the article of Dr. A. Pines and his colleagues (27 May, p. 543) with interest. I cannot agree, however, that colistin has no place in the treatment of purulent exacerbations of chronic bronchitis. At least 50% of the patients treated with colistin[1] by inhalation at this hospital were chronic bronchitics, with acute purulent exacerbations of their condition.

Since the winter of 1965–6 *Pseudomonas pyocyanea* infections have ceased to be a problem in this hospital.—I am, etc.,

Crush Injuries of the Chest

SIR,—We would like to reply to some of the points raised by Dr. J. M. Leigh in his letter (6 May, p. 374). Apart from the early cases in our series, we have measured Pa_{O_2} (or Sa_{O_2}) in all our patients, and the results obtained were invariably low when the patients were breathing air.

Referring to those patients who have a low Pa_{O_2} and a low P_{CO_2}, Dr. Leigh says, "Any beneficial effects of intermittent positive pressure respiration (I.P.P.V.) in such a patient are due to a lowering of V_{O_2} as a result of the abolition of respiratory effort and sedation produced by the drugs given, and also the alleviation, to a certain extent, of atelectasis by the positive pressure." From the point of view of blood gas results this is largely true, although reduction of any pulmonary oedema or congestion present will also raise the Pa_{O_2}.

However, we feel that the benefits of I.P.P.V. extend beyond the correction of abnormal blood gas values. I.P.P.V. affords greater patient comfort, both by preventing painful over-riding of fractured ribs and by permitting the use of adequate doses of analgesics. The early use of I.P.P.V. will tend to obviate the later development of the "wet-lung" syndrome. Furthermore, the use of I.P.P.V. by effecting the internal splinting of the fractured ribs prevents subsequent gross deformity of the thoracic cage.

Dr. Leigh also refers to the possible deleterious effects of I.P.P.V. on cardiac output and cerebral blood flow. Our usual practice is to use the minimum positive pressure commensurate with adequate ventilation. However, the pressure required depends on the state of the lungs, and if the compliance is low, high inflationary pressures are necessary. If severe hypotension does occur as the result of I.P.P.V., this is treated with vasoconstrictor drugs.—We are, etc.,

Accident Services

SIR,—Mr. Daniel Lamont's letter (6 May, p. 374) raises questions which are of fundamental importance to ambulance services, to first-aid teaching, and to the need for hospital-based flying squads to give on-the-spot resuscitation. I have tried to get recent evidence of the causes of death in those brought in dead following road-traffic accidents in this county, and have failed to find hard facts which could be used to decide how many of these deaths could be averted by medical care subsequent to the injury.

Pathologists vary in their estimates of deaths from airway obstruction — some putting the figure as high as 25%; others, regarding agonal vomiting as a "normal" finding, give a lower percentage. Neurosurgeons cite pneumonia due to inhaled vomit or secretion as the commonest cause of death following head injuries in which the brain damage does not kill the patient. The number of deaths from airway obstruction and from the inhalation of vomit or secretions can be influenced by good first aid.

Some deaths may occur at the scene of an incident, and some casualties could not be saved by any techniques available today. What percentage of the total do these cases represent? What is the role of airway obstruction, bleeding, and other causes in such deaths? And, out of those found alive at the scene of an incident, how many could be kept alive by a combination of first aid and resuscitation? What are the causes of death during the ambulance ride? What percentage of these deaths is preventable? And what action is required to improve the existing situation?—I am, etc.,

A. WARD GARDNER.

Esso Refinery,

Unexpected Foreign Body

SIR,—I wonder what percentage of dentures are made with radio-opaque material?

This week a patient presented himself at the surgery with a persistent cough present for about four months. Four months ago he had an accident at the pit during which he was knocked unconscious. He missed his dentures at the time but did not think it worth mentioning to me. Since then he has been in and out of the surgery with a cough, purulent sputum, etc. An *x*-ray of the chest six weeks ago was negative. Yesterday during a most violent paroxysm of coughing he coughed up his dentures, which measured about 2 in.×½ in. (5.08 cm.×1.27 cm.) and came, presumably, from his trachea.

He has since then had a repeat chest *x*-ray, once more negative, and also an *x*-ray of his dentures, which were not opaque. Surely this is dangerous and such dentures should not be allowed to be made.—I am, etc.,

G. STEIN.

Sutton-in-Ashfield,
Nottinghamshire.

Intrauterine Contraceptive Devices

SIR,—I have read with interest the article on intrauterine contraceptive devices in the "Current Practice" series, written by Dr. J. Frampton and Mr. D. Mathews (10 June, p. 683). Since they mention the Saf-T Coil but have no figures available yet, I think this is a good time to mention to you the preliminary findings of a series I am doing.

The patients are drawn from the Oldchurch Hospital gynaecological department and the Westminster Branch of the Family Planning Association.

During the year June 1966 to May 1967 162 patients were fitted with a Saf-T Coil 33S. This is the device with the double spiral and two nylon threads in the cervical canal. A total of 694 woman months have been recorded. The expulsion rate and removal rate compare very favourably with the published figures of other devices. Two devices have been expelled, both two months after insertion during a menstrual period.

Seven devices have been removed: one after nine months as a further pregnancy was desired; one after one month for sepsis (this device was inserted early in the puerperium); five for menorrhagia (three of these were noted to have menorrhagia before).

Of this series, 12 patients had already expelled Lippes Loops C. Four of these had expelled them on two occasions. Two other patients had already tried Lippes Loop C but the device had been removed for menorrhagia. Two patients had tried Birnberg bows, but these were removed for menorrhagia. Thus in this series a total of 16 patients had already found other devices unsatisfactory.

As many of the patients wished for maximum protection from pregnancy they were offered the opportunity of using Emko foam as well, but it was discovered that most of these discontinued the foam after the first two months. A total of 33 patients elected to use the foam. One patient in this series has become pregnant.

A total of 497 woman months have been observed where the Saf-T Coil alone was the only method of contraception. This compares very favourably with the pregnancy rate of other devices. It is interesting that the two expulsions and the pregnancy occurred in patients who were fitted with their devices in the months of January, February, and March this year when the fixed red marker on the introducer had been changed to an adjustable one. I feel that these three devices may well have been inserted too low into the uterus, and since this technique has been adjusted no further expulsions have occurred.

This preliminary report suggests that the Saf-T Coil may well have a lower pregnancy rate and expulsion rate than other devices so far reported.—I am, etc.,

KATHLEEN FRITH.

Oldchurch Hospital,
Romford, Essex.

SIR,—May I add our experience with the Saf-T-Coil 33-S to your very helpful article on intrauterine contraceptive devices by Dr. John Frampton and Mr. Dudley Mathews (10 June, p. 683).

In this practice I have now inserted 50 Saf-T-Coils, covering a period of approximately 200 woman months, and have been more than favourably impressed by:

(1) The ease of insertion; there have been no failures to introduce the coil.

(2) No cervical dilatation has been found to be necessary in any case.

(3) None have been expelled.

(4) Patient acceptability. There have been no requests to remove the coil.

(5) The advantage of a complete unit in a pre-sterilized pack, which means there is no need to sterilize any other instrument.

(6) Last, but not least, no pregnancies to date.—I am, etc.,

J. STUART BROWN.

West Malling,
Kent.

Hypophysitis and Hypopituitarism

SIR,—The description of the case of hypophysitis and hypopituitarism by Drs. R. Hume and G. Hefin Roberts (27 May, p. 548) certainly suggests an autoimmune basis for the disease. A number of patients with hypopituitarism for which no cause has been found have been studied at Charing Cross Hospital. Sera have been sent to my colleagues with the suggestion that pituitary antibodies might be present. Preliminary investigations only have so far been made, but clearly pituitary antibodies should be sought in patients with idiopathic hypopituitarism. —I am, etc.,

P. B. S. FOWLER.

London W.1.

"Cruachan"

SIR,—The article on "Cruachan" (17 June, p. 758) was of great interest to me. In London a hostel for diabetic children, now at Palingswick House, Hammersmith, has long experience of the problems mentioned in the article and has been dealing with them, since its foundation, originally at Hutton during the war (1939–45), when the need presented itself for special arrangements for diabetic children in the evacuation period.

It is the experience of this Inner London Education Authority hostel that an increasing number of the children needing such provision show, in addition to the diabetes, various disorders of behaviour and very frequently a social problem also.

Only a small proportion of diabetic children need hostel accommodation, and for differing lengths of time, but for those who do there can be little doubt that it is a valuable measure, and most of them learn quickly to manage their own diabetic life.—I am, etc.,

A. B. STEWART,
Medical Adviser,
Inner London Education Authority.

County Hall,
London S.E.1.

A Matter of Principle

SIR,—The recent Conference of Local Medical Committees (24 June, *Supplement*, p. 177) has gone down in history as officially recording an overwhelming vote against the "principle" of payment for special experience and service. This must surely, without doubt, be the most incredible and shameful decision ever taken by a conference of learned professional men living in a democracy. I am glad that my name was recorded as voting against it. There were a few of us there who felt that this was an extremely serious matter of principle, and unfortunately the conference saw fit to allow none of us to put any opposing view forward. Presumably the profession will now ask the Government to cease paying any vocational training allowances, as these allowances are entirely payment in recognition of special experience. Presumably, also, we shall now ask that doctors on the obstetric list will be paid at the same rate as doctors not on the obstetric list.

That this shameful state has arisen is, I am sure, entirely the fault of members of the General Medical Services Committee who phrased the wording of the referendum. I sincerely believe that the vast majority of people who voted in the referendum do not really disbelieve in the principle of rewarding merit, and that they were answering an entirely different question. The question which they answered, and which I believe is the question which should have been put, is, "Do you believe that it is possible to devise a completely fair scheme for distributing merit awards in a way suggested by the Working Party?" Had this been the question put, I am sure that there would have been an almost 100% answer of "No."

I wonder what will be the feelings and thoughts of any young doctor about entering a branch of the profession which has stated overwhelmingly it does not believe in the rewarding of merit? I believe, and I know that I am not alone, that if the conference had been willing even to consider—which it was not—a scheme for the direct and automatic reward for the possession of certain criteria it might have been possible to persuade the Government to give favourable consideration to using the £2½m. This is already done in the armed Forces and public health services by the payment of extra money for the possession of diplomas. Once the Ministry and the profession had agreed what attributes they would like to see the general practitioners possessing I do not see how any Government could fail at least very carefully to consider the rewarding of these attributes directly. Now that the fear that a scheme involving selection and secrecy might be imposed on the profession has been removed, I hope and trust that every general practitioner will spare a few minutes seriously to consider the real implications of this appallingly bad decision taken at the recent conference. Then perhaps pressure can be brought through the local medical committees to see to it that, while rejecting the Working Party's proposal, it again becomes the policy of family doctors that as a matter of principle whenever possible and practicable merit shall be rewarded.—I am, etc.,

Talgarth, Brecs. J. M. LONDON.

B.M.A. Action

SIR,—My motion that modern techniques of sampling public opinion should be used by the B.M.A. to find out whether the public thinks enough money is being spent on the N.H.S. was carried without a dissenting vote by the Junior Members Forum.[1] As Dr. J. F. Pigott said, nothing would be gained from this if Mr. Enoch Powell was right in saying[2] that present expenditure reflects electoral opinion. But Mr. Powell's argument that the constancy of N.H.S. expenditure must reflect electoral opinion is a *non sequitur*. If both major political parties have the same policy on this the electorate is gagged. Their real opinions can be brought to light only by research. A trace of action here would achieve more than years of talk. Since the Ministry (if it agrees with Mr. Powell) has the onus of proof and the B.M.A. that of disproof, they should co-operate in the experiment.

If raising the N.H.S. budget were electorally popular would not one or both parties have included it in their platform? That presupposes an infallible clairvoyance by politicians that has sometimes failed them in the past. The N.H.S. is assumed to be good enough if the public makes few complaints. The answer is put the public in the picture first and then ask if the N.H.S. budget is adequate. The taxpayers have to judge whether the N.H.S. should have priority over other claims on the revenue. We do not know for sure what their verdict would be. But if they supported the B.M.A.'s view that more money should be spent on the N.H.S. the profession would have a vastly more powerful weapon than it had ever had, since public opinion is the dynamite that moves Governments.

Many doctors think the extra money urgently needed by the N.H.S. should come from direct payments by patients. But it is generally thought that the majority of the electorate believe that medicine should be financed out of taxes, not by direct payment. Would not the future of medicine be far brighter if doctors and patients were united on this? The last Tory Minister of Health dismissed direct payment in one sentence. Do we seriously think Mr. Kenneth Robinson will be more amenable?—I am, etc.,

Bristol Royal Infirmary,
Bristol.
R. S. CORMACK.

Recognizing Experience

SIR,—Much has been heard recently about efforts to reverse the "brain drain" of doctors. My present predicament highlights one reason why these are unlikely to be successful.

In New Zealand I held a registrar appointment for nine months and was for three months a senior house-officer at the Postgraduate School of Obstetrics and Gynaecology in the University of Auckland, a post which is recognized by the College in this country. On my return I took an appointment as senior house-officer, necessary for approved training purposes, and applied for protection of salary through my regional board. The reply they received from the Ministry stated that there are no provisions for reckoning experience outside the hospital service in this country for incremental purposes.

It seems strange to find that in a so-called "national" service a colleague from the same hospital in Auckland, when he first came to work in this country, was allowed full credit for his experience.

I wonder how many others have had such preferential treatment and how many like myself have had experience shunned, perhaps because they have had the misfortune to work for one of the less sympathetic regional boards.

Obviously you must choose your regional board carefully, and those lured from overseas to return to the N.H.S. should be aware that the experience thus obtained, unless under the auspices of the Ministry of Overseas Development, is of no value to the N.H.S. and they would be well advised to stay where it is appreciated.—I am, etc.,

Luton and Dunstable Hospital,
Luton, Beds.
R. H. T. WARD.

Is There a Shortage?

SIR,—One year ago the Seventh Report of the Review Body on Doctors' and Dentists' Remuneration[1] contained the observation (paragraph 59, iii): "There is no sign . . . that there is any difficulty in filling (consultant) appointments."

However, the Joint First Report on the Negotiations with N.H.S. Hospital Doctors and Dentists (*Supplement*, 27 May, p. 135) includes the following: "The Department pointed out that some existing consultant posts were difficult to fill. . . . They undertook to invite . . . all boards to re-advertise vacant posts."

There seems to be an inconsistency here which calls for an explanation from the Ministry.—I am, etc.,

ROBERT J. EVANS.

North West Surrey Group Laboratory,
St. Peter's Hospital,

Merit Awards to Hospital Staff

SIR,—The attitude of hospital staff towards merit awards is at present being assessed by a postal ballot conducted by the British Medical Association, and the position concerning these awards has also been dealt with by letters in the *Daily Telegraph* of 16 June *et seq.*

If merit awards are to continue, and there may be a case for this, it is clear that it is generally felt that the present secrecy which surrounds them should be abolished, and they should be fair and seen to be fair, and that all senior hospital staff wherever employed and all regions should be treated equally. These standards can be achieved in two ways:

(1) By "paying the rate for the job." For example, a professorial chair of surgery would presumably be paid at a higher rate of salary than other surgical appointments. Further, this higher rate would apply equally in London, Bristol, or Aberdeen Universities, or others.

(2) Each consultant, S.H.M.O., and registrar, and perhaps administrative medical officers in the hospital service, should have a "personal merit rating" and the markings, as officially laid down on this rating, should be known to him. The marking could be made on the following sort of basis:

(*a*) Research or development work carried out. This assessment to be made by an award council in the specialty concerned.
(*b*) Teaching commitments.
(*c*) Clinical or administrative responsibility.
(*d*) Seniority and experience in the specialty.
(*e*) Higher professional qualifications.
(*f*) Committee services. Assessments to be by regional boards.

If such a system were adopted many of the present anomalies would be overcome and every man would benefit according to the merit rating to which he was entitled. The ethical objections to the secrecy of the present system and the patronage which it of necessity brings in its train would be resolved.—I am, etc.,

Winchester, Hants. C. REMINGTON-HOBBS.

New Constitution

SIR,—Much has been written and said by many for years now on the matter of a new constitution. The Memorandum by the East Yorkshire Branch (*Supplement*, 3 June, p. 143), in the opening paragraph referring to the Revised Report on the Constitution, states: "It should be viewed as a battle in the 100 years' war between the centre and the periphery for power." This surely is what the whole thing is all about. As long as we are all fighting among ourselves our real opponents will continue laughing. We have a great need to foster understanding and to effectively co-operate all along the line, so that members see justice done by a fully effective fighting force, with representation and representatives and leaders in whom we can all have confidence. Surely only by proportional representation, as far as practically possible, can we even have that power of overwhelming membership which would come when the profession with unity speaks with one voice. A strong organization would automatically attract members to it. The new constitution seeks to do this. I firmly believe that at this stage the memorandum by East Yorkshire can only hope to cause further delay in what is long overdue. Further delay must be dangerous.

East Yorkshire fears that power will be taken from the periphery. I hope that East Yorkshire will carefully consider Motion 340 by City of Aberdeen: "That the Scottish representatives on the Representative Body should be nominated by the Scottish Council." There are obviously differing problems in different areas, otherwise there would not be such a wide range of opinions.

Idealists and realists who will not settle their differences often end up with revolution. Revolution within the Association might have undesirable, unforeseeable, and uncontrollable effects. The solution to this particular problem must surely be something that tries to balance the swinging pendulum of opinion.—I am, etc.,

C. C. LUTTON,
Honorary Secretary,
East and Midlothian Division,
British Medical Association.

Musselburgh, Midlothian.

Invasion of Privacy

SIR,—In due course I shall be forced under section (5), paragraph 7, part I, schedule I, *Statutory Instruments*, 1966, No. 1210, to accept entry of a local doctor to inspect my practice premises, which are in my private home.

My wife and I have always regarded this term of service as an invasion of personal privacy and ethically and morally wrong. Surely it is about time this term of service was deleted in just the same way as the "test prescription" term of service was deleted on moral and ethical grounds.—I am, etc.,

Southampton, Hants. J. G. TEES.

General Practice

SIR,—As a principal in general practice who finds himself ten years qualified this month, I have been reflecting on the matters which perplexed and distressed me during my progress towards becoming established. On qualifying M.B., Ch.B. I little realized how ill-prepared I was for general practice. My Alma Mater had provided me with no special tuition for this branch of my profession. I didn't know an E.C.10 from an O.S.C.1, and was ready to be exploited by public and patient alike.

I was quite naive about my obligations and rights as an assistant or principal. The legal aspects of partnership or assistantship agreements, despite their importance, were a complete mystery to me. At that time, of course, there was unemployment among doctors, and written agreements were often overlooked. An assistant often had to accept without question a dangerously high proportion of the work of the practice without adequate training or experience. The salary was £800 per annum and you provided and ran your own car out of it. Rotas were unheard of, and four hundred applicants for a practice vacancy was not uncommon.

During the last ten years I have waited in vain for the establishment to produce a mandatory basic contract or agreement for assistants and junior partners; to guarantee a minimum stipend for assistants and a minimum proportion of partnership profits for junior partners; to guarantee that a junior partner reaches parity with his fellow partners within a reasonable length of time; to guarantee that all junior partners receive a written agreement; and to outlaw once and for all the concealed sale of goodwill. These guarantees would make general practice a much more attractive calling for the young man who wants to settle down and make a career of it. But the G.M.S.C. have refused to take definite action on the grounds that the affairs within a partnership are only the concern of the partners themselves, and beyond the terms of reference of that committee. What a fatuous position to adopt on such a fundamental issue involving the careers of so many general practitioners.

Apart from the organization of refresher courses, the Royal College of Practitioners has made no impression on me at all during my ten years since graduation. Yet this is the very body which one would have thought would have pioneered a career structure for young general practitioners in this country, just as the other Royal Colleges have done in their own fields. I am forced to assume, therefore, that the College is happy with the *status quo*.

I am bound to agree that most of my criticisms would be answered by the introduction of a salaried service, yet I myself have many reservations about this, as I feel that my status would be reduced to that of a local authority medical officer. If, however, there were guarantees that my position and clinical freedom remained as at present, and if I were assured that the G.M.S.C., the Council of the B.M.A., the Annual Conference of Local Medical Committees, the Royal College of General Practitioners, and the Ministry of Health would all be abolished, and that general practice would be run as an independent corporation along the lines of B.O.A.C. or the Electricity Board, beyond the influence of the politicians, then I would agree to a salaried service. Then I would feel that the next ten years, for a man graduating in 1967, would present a much more stable and attractive career than the last decade presented to me.—I am, etc.,

Glasgow S.3. DUNCAN STRANG.

Ice-cream Van Accidents

SIR,—In our experience here a not uncommon cause of head injury in young children has been the acute suppression of caution and road drill by the prospect of ice-cream. They have usually been hit by passing vehicles when, at the sound of the bell, they rush blindly to the van to purchase, or as they run back home to consume.

We should be interested to hear from your readers whether this special type of accident is widespread throughout the country. If it is, some publicity might encourage its prevention.—We are, etc.,

M. BRIGGS.
JOHN M. POTTER.

Accident Service,
Radcliffe Infirmary,
Oxford.

"Intimations of Immortality?"

SIR,—Graduates of this university must have felt a glow of pride to see Lister's original paper of 1867 reprinted in the *B.M.J.* (1 April, p. 9). Less gratifying have been the continuing requests for reprints that have subsequently come here addressed to Dr. Joseph Lister, University of Glasgow, Glasgow, Scotland. Your readers may wish to ask themselves whether this mode of address should be regarded as a subtle and graceful compliment to Lister's immortality, or merely points a moral to both those who issue and those who receive requests for reprints.—I am, etc.,

The University, Glasgow. C. M. FLEMING.

Obituary Notices

J. ST. GEORGE WILSON, M.C., M.B., CH.M., F.R.C.S., F.R.C.O.G.

Mr. J. St. George Wilson, formerly a consultant obstetrician and gynaecologist in Liverpool, died on 4 June, at the age of 76.

John St. George Wilson was born in China on 8 April 1891, and received his medical education at Liverpool University, graduating M.B., Ch.B. in 1914, and taking the Conjoint diploma in the same year. He served in the Army during the first world war, and after demobilization began training as an obstetrician and gynaecologist. He held resident and registrar appointments successively at the Liverpool Royal Infirmary and the Shaw Street Hospital for Women, and studied for a time in Vienna. In 1921 he was admitted Fellow of the Royal College of Surgeons of England and was awarded a mastership in surgery by his own university. His ability and industry were such that by 1925 he held appointments as honorary assistant obstetrical and gynaecological surgeon at the Liverpool Royal Infirmary, and honorary assistant surgeon at the Liverpool Maternity Hospital. Later he was appointed consultant obstetrician at Walton Hospital, and also joined the consultant staff of the Hoylake and West Kirby Cottage Hospital. He was a foundation member of the Royal College of Obstetricians and Gynaecologists and was elected to the Fellowship in 1933. During the nineteen-twenties onwards he was one of the outstanding obstetricians and gynaecologists in the north-west, and well known throughout the country. He was a member of the Gynaecological Club, and rarely missed a meeting of the North of England Obstetrical and Gynaecological Society.

T. N. A. J. writes: The North of England Obstetrical and Gynaecological Society was always lively, and never more so than when St. George Wilson was present. His quick brain and ready wit made him a master of repartee if not debate. His views were always definite, and he never hesitated to express them in forthright if few words. In him courage overruled discretion; this earned him a Military Cross during the first world war, but, combined as it was with brusqueness, often made him enemies later.

Despite this St. George Wilson was a great man, having vision as well as knowledge, and being a first-rate clinician and surgeon with an extensive experience. His gifts were such that he could have achieved anything that he wanted, anything from a large practice to positions of administrative importance in the profession. But he did not want such things. St. George Wilson found it impossible to conform; he liked to be different for the sake of being different, to disagree even when he subconsciously agreed. He enjoyed being a lone wolf and he was pre-eminently a "no" man. It was these characteristics which made him in August 1948 retire from his hospital appointments long before his time had expired. He could not stomach working under the conditions of a National Health Service. Yet before he went he took care to arrange matters so that the newly created university whole-time team could take over his unit at the Liverpool Royal Infirmary. It was such magnanimous actions, and care for the interests of his juniors, as well as his extraordinary ability, which endeared him to those who knew him best, and this despite his foibles.

After leaving his professional activities St. George Wilson became a farmer or market-gardener, but his restlessness persisted. At no time in his life, it is said, did he live in the same house for more than three years at a time. For one short period he lived in South Africa. His disappearance from the scene during the last twenty years resulted in the fact that few of the present generation of obstetricians and gynaecologists know his name, and extremely few realize what they, and obstetrics as a whole, owe to him. It was St. George Wilson who led the way in the revolution in obstetric practice which was a feature of the 1920–40 period. Brought up in the old school, he adopted and created new approaches. He tried out every new management of toxaemia as it was introduced. He was a leader in antenatal care, conducting each one of his clinics personally. His book *Prenatal and Postnatal Management*, which appeared in 1937, even included all details of antenatal as well as postnatal exercises.

St. George Wilson's greatest contribution to the literature was his article "Lower Uterine Segment Caesarean Section," which appeared in the *Journal of Obstetrics and Gynaecology* in 1931. In this he described fifty consecutive operations carried out personally since 1926 using the transverse incision in the lower segment. These operations were carried out late in labour in neglected cases, often infected, and long before sulphonamides or antibiotics were discovered. Only one patient died. The lower segment operation had been carried out previously in three or four isolated cases in Britain, and more frequently in other countries, but his was the first series of operations to be performed in this country. Moreover, he perfected his technique to such an extent that he was prepared to treat patients by trial of labour rather than by elective section, to employ the operation for conditions such as prolapsed cord and placenta praevia, and to make it take the place of difficult vaginal delivery and the then traditional obstetric manœuvres. The introduction of lower segment caesarean section into Britain is often credited to the late Charles Marshall. This is incorrect. Marshall, and all the other younger obstetricians working in Liverpool in the early 1930's, learned the operation from St. George Wilson and followed his teaching implicitly. The gospel spread across the north of England, and ultimately pervaded the whole country. As a result it can be claimed that St. George Wilson more than any other individual was the father of modern obstetric practice, at least as it applies to Britain. As a gynaecologist, too, St. George Wilson was among the best. Technical skill alone was not enough for him; he paid attention to medical gynaecology, and especially to pathology. Indeed, he never accepted a pathologist's report on tissues removed without examining each section himself.

That this man, who contributed so much to obstetrics, should of his own volition disappear into obscurity for the last twenty years of his life was tragic. Yet it is typical of him. Indeed, if he were alive today he would forbid any tribute or any mention of his achievements. To those of us who knew and admired the man despite all his quirks it is important to place on record his greatness, if only to make modern obstetricians realize to whom they owe their present good fortune of practising obstetrics in a relatively easy and safe way. We should remember him, as well as his wife, his daughter, and three sons, who survive him. One of his sons is a member of the medical profession.

E. H. T. CUMMINGS, C.B.E., D.C.L. M.D., D.P.H., D.T.M.

Dr. E. H. T. Cummings, a former senior medical officer in the Colonial Government of Sierra Leone, died suddenly on 17 June in Freetown, Sierra Leone. He was 76.

Eustace Henry Taylor Cummings was born in Freetown in 1890. He came to Britain in 1912, and was one of the first Africans to read medicine at the University of Liverpool, where he qualified with the Conjoint diploma in 1917, graduating M.B., Ch.B. in 1918 and taking the D.P.H. in the same year. He had a distinguished academic career, and was awarded the John Garrett international fellowship in bacteriology for 1918–19 and the M.D. was conferred on him for his thesis in that year, when he also took the D.T.M. After serving house appointments, including the post of additional police surgeon in Birmingham, he was appointed by the Secretary of State in 1920 as medical officer, Sierra Leone. In 1941 he was appointed M.B.E. In 1944 he was made a member of the Elliot Commission on higher education in the Colonies, and whose report and recommendations resulted in the establishment of the Universities of Ibadan and of Ghana. He and the late Arthur Creech-Jones, M.P., played an active part in insisting that Fourah Bay College, now the University of Sierra Leone, and the oldest institution of higher learning in West Africa, should be retained as a university college of Durham University and developed into an autonomous university.

This has now been accomplished. After retiring from the Colonial Medical Service he served on the council of Fourah Bay College, and his services were recognized by the conferment of the honorary D.C.L. of Durham University in 1960. He was in active professional practice up to the day of his death.

Dr. Cummings served for five successive years as Mayor of Freetown, and in 1952 was appointed C.B.E. for public service. He was president of the Sierra Leone Branch of the British Medical Association in 1955.

Until recent years Dr. Cummings was a frequent visitor to Britain, and was a well-known figure in both London and Liverpool. He is survived by his wife, Janet, and by a son and daughter.—I. G. C.

F. G. L. BARNES, M.B., B.S., D.P.M.

Dr. F. G. L. Barnes, a former senior medical officer for mental health under the Ministry of Health and Local Government of Northern Ireland, died at his home in Cultra, County Down, on 17 June. He was 76.

Francis Gregory Lawson Barnes was born in Clarborough, near Retford, Notts, on 12 March 1891, and received his medical education at St. Bartholomew's Hospital, London, qualifying with the Conjoint diploma in 1921. He had a distinguished academic career, and was gold medallist of his year. Early in his career he evinced an interest in psychiatry, and took the D.P.M. in 1924. He graduated M.B., B.S. in 1930. After appointments as physician in charge of the psychiatry department at Poplar Hospital, and psychiatric consultant in St. Andrew's Hospital, Bow, he was appointed physician superintendent of Long Grove Mental Hospital, Epsom, in 1934, from which post he retired in 1951. At that time he was invited to become senior medical officer (mental health) to the Ministry of Health and Local Government, Northern Ireland, and served in that capacity from 1951 until 1958. Although at that time he was almost 67 years of age, he enjoyed excellent health and continued to give valuable service in a part-time capacity as a specialist in mental health to the Ministry's regional medical service and was able to continue in this work until some months ago.

Dr. Barnes was an excellent clinician and right up until his illness his reports, whether on clinical matters or on mental health policy, were of the highest order. He settled down happily in Northern Ireland, and was held in affectionate regard by all his colleagues. Although confined to the house for several months, he bore his illness with patience and fortitude. The deepest sympathy of his many friends and colleagues will be extended to his devoted wife and son.—F. F. M.

W. D. N. writes: Freddie Barnes, as he was affectionately called in the L.C.C. Mental Hospital Service, has been a friend of mine since 1913 when we were in "digs" together as medical students at St. Bartholomew's. He was three years my senior, and should have qualified at the beginning of the first world war. However, the financial stringencies of the medical student prompted him to take the Certificate B in the O.T.C., to which was attached a handsome gratuity in those far-off days. The result was that Barnes joined the Army Reserve and was commissioned in the King's Own (Liverpool) Regiment. He was quickly sent overseas and was very severely wounded in the battle of the Marne. He saw no further active service but spent the rest of the war in an infantry training depot at Plymouth. It was not till after the armistice that he returned to Bart's to complete his medical education. I again came into close contact with him as a medical colleague and he was my first deputy at Horton Hospital, and after three years he was promoted to succeed David Ogilvy in charge of Long Grove Hospital. Barnes was a competent psychiatrist and a good administrator. Though a strict disciplinarian, he was popular with both patients and staff. He was a delightful colleague and one of the most loyal one could wish for.

R. S. REID, M.B.E., M.B., CH.B.

Dr. R. S. Reid, formerly in general practice in Bath, died in hospital on 10 May. He was 77.

Robert Scott Reid was born on 8 May 1890, and was educated at Glasgow High School and University. At the university he was a contemporary of Walter Elliot and Osborne Mavor (James Bridie). He played rugger for the university first fifteen, and had an international trial for Scotland. Versatile as he was, even in his young days, he also played soccer for Queen's Park. His studies were interrupted by the first world war, and after demobilization with the rank of lieutenant he returned to the university, graduating M.B., Ch.B. in 1920. The following year he set up in practice at Bath, where he remained for 46 years. He was honorary surgeon to the Bath Rugby Club for that time and president of the club on two separate occasions. He was also medical officer to the Bath Football Club, medical officer to the Bath Red Cross, and divisional surgeon of the St. John Ambulance Brigade. During the second world war he was medical officer to the Admiralty at Bath. In 1947 he was appointed M.B.E., and in 1962 was invested as commander of the Hospital of St. John of Jerusalem.

C. R. G. writes: The doyen of the medical profession in Bath, Bob Scott Reid was the perfect example of "the real old family doctor." In 1921 Bob came to practise in Bath, and it was there that his real versatility was given the opportunity to flourish. He was an exceptionally able general practitioner, an outstandingly good obstetrician, and a doctor who gave the utmost confidence to all his patients. He was small in stature, but a giant in heart and mind. He was gentle and reassuring to the old and "a genial uncle" to the young. In both these spheres he earned his niche as medical officer to the old people's homes, and medical officer to the children's homes.

Despite his large practice and his constant devotion to his patients, Scott Reid found time for many activities in sport and in first aid. This he did at the expense of his own leisure time. He hardly ever had what might be regarded—and expected—as "a decent holiday." He was known throughout the West Country as an outstanding bowler. He represented Somerset County for many years, and played in international bowling trials in 1935 and 1936. He was president of the Somerset County Bowling Association and of the Bath Bowling Association. In the field of first aid Scott Reid had the highest reputation.

Bob had a host of friends in Bath, and they will miss him very greatly. His keen sense of humour and his amazing fund of stories would cheer up any of us on the cloudiest of days. His immense courage could not be daunted even by the serious illness and suffering of the past months. He would not give in, and was visiting patients up to three days before he died.

He is survived by his wife, Gertrude, and by a son and daughter, to whom we extend our deepest sympathy.

R. B. McCOLL, M.C., M.B., CH.B.

Dr. R. B. McColl, a general practitioner at Hanmer, Flintshire, died suddenly at his home on 26 April. He was 71.

Robert Balderston McColl was born in Paisley, Renfrewshire, on 26 January 1896, and received his medical education at Glasgow University, graduating M.B., Ch.B. in 1924. He started practice in Hanmer in 1926, first in partnership with the late Dr. Clark, and subsequently he was in partnership with his brother, the late Dr. Hugh Ernest McColl, O.B.E., from 1947 until 1964. He was still actively engaged in medical practice at his death. During the first world war Dr. McColl held a commission in the Highland Light Infantry. He was awarded the 1914–18 Star, and was subsequently awarded the Military Cross in France for his gallantry and distinguished service in action. He saw service both in France and at Gallipoli. After demobilization with the rank of captain he returned to general practice. During the second world war he gave much of his time to lecturing for the Red Cross. He took an active interest in the British Legion's activities and was a past vice-president. Dr. McColl held several local appointments, and was visiting physician to the Ellesmere Cottage Hospital. He was secretary and treasurer of the Denbigh and Flint Division of the British Medical Association from 1949 to 1954, and chairman of the Division in 1948–9 and again in 1960–1. He was also a member of the Wrexham Clinical Society and of the Chester and North Wales Medical Society.

Dr. Robert McColl was a well-known figure throughout north-west Shropshire, and his death will be mourned by many hundreds of patients and friends alike. He devoted a considerable amount of his time towards raising funds for the restoration of his local church. He maintained the highest standards of medical practice, and was not only an excellent physician but a respected and kindly friend to all his patients.

He is survived by his wife, Julie, and his two sons, Anthony and Colin, to whom all his friends and colleagues offer their deepest sympathy.—H. G.-T.

News and Notes

EPIDEMIOLOGY

Lead Poisoning at Bradford

Two sisters aged 3 years and 2 years were admitted to Bradford Children's Hospital on 11 June 1967 suffering from convulsions. There was no history of epilepsy, and five other siblings were well. There were no findings to support a specific diagnosis. A clinical suspicion of poisoning was reinforced by the history that a number of animals in the neighbourhood had recently died with convulsive symptoms. This was reported to the Medical Officer of Health for investigation.

The home and its surroundings were visited on 13 June. In the back yard there were remnants of burnt battery casings and ash. The weather was warm, and it was stated that no burning of battery cases had occurred for two to three weeks, but that there had been previous burning for a period of approximately three months. A house-to-house visit revealed several properties where burning had taken place, substantial quantities of remnants and ash being widespread. At the same time an inquiry was made into illnesses of the occupiers and their pets. Subsequently the people were invited for clinical and haematological examination. Radiological investigation is proceeding. The major source of the battery casings was in a disused scrap yard with access through a broken fence. In the succeeding days three smaller dumps were found scattered through the industrial parts of the area.

Investigation of the two children showed punctate basophilia and characteristic lead lines on *x*-ray examination. The children, whose fits were initially controlled with paraldehyde, had further convulsions, and despite treatment with an infusion containing calcium disodium versenate (30 mg./kg. body weight) on 14 June both died in the early hours of 15 June.

Clinical Findings

As a result of the initial examination of 60 residents in houses where it was admitted that batteries had been used for fuel, five children and two adults thought to have evidence of lead poisoning were admitted to hospital.

Case 1.—Girl aged 2 years. Anorexia during previous week. Vomiting on day of examination. No clinical abnormality, haemoglobin level of 9.6 g. per 100 ml. Marked stippling, reticulocytosis, and late normoblasts. *X*-ray of long bones showed dense zones at metaphyses consistent with heavy metal poisoning.

Case 2.—Girl aged 2 years. Asymptomatic except for incoordination of eye movements. Basophilic stippling. *X*-ray examination showed dense zones at the knee regions approximately 2 mm. thick and at the wrists about 1 mm. thick.

Case 3.—Girl aged 3 years. Clinically well, but haemoglobin level was 9.5 g. per 100 ml. Marked basophilic stippling and reticulocytosis. On *x*-ray examination there were zones of increased density at the growing ends of long bones.

Case 4.—Girl aged 10 years. No clinical abnormality. Basophilic stipple cells, and on *x*-ray examination zones of increased density were present.

Case 5.—Girl aged 5 years. Admitted to hospital because of abdominal pain and vomiting. Blood films did not show evidence of toxicity but zones of increased density were present on *x*-ray of long bones.

Case 6.—Woman aged 39, who continued to burn batteries despite a warning two days earlier, developed acute abdominal pain, paraesthesia, and ataxia on 17 June.

Case 7.—Boy aged 14 years. Developed acute abdominal colic and paraesthesia in his hands on 16 June.

In addition three adults were admitted as doubtful cases, with presenting symptoms of jaundice (Case 8), neurological symptoms (Case 9), and mental illness (Case 10). There is no confirmation that lead poisoning is contributory. A further 160 people in the area, free from symptoms but with a history of occasional use of battery cases, are being examined; several positive *x*-ray findings are known, but detailed findings are not yet completed.

Comments

This incident confirms the dangers arising from the burning of battery cases. The plastic case is probably non-toxic, but substantial quantities of lead salts are adherent to the case. In 1955 J. A. Gillet[1] reported on an outbreak of lead poisoning at Rotherham. Our initial investigation agrees with his that the most likely vehicle of poisoning is the toxic ash remaining after burning, the ash being probably ingested and possibly inhaled. An unusual number of deaths in domestic pets had occurred in the weeks preceding the outbreak.

The danger could be averted by proper disposal of battery casings as a matter of normal commercial practice, and indiscriminate dumping would be amenable to legislative control. All these cases occurred in an area where difficult social and economic problems exist.

PARLIAMENT

Powers of Search to Control Drug Peddling

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Two changes are to be made in the Dangerous Drugs Bill during its progress through the House of Lords, where it was given a second reading on 20 June.

The first relates to the safe keeping of drugs, and the second to the powers of search. On the first, LORD STONHAM, Under Secretary to the Home Office, said the Home Secretary had recently consulted the representative bodies of the pharmaceutical industry and pharmacists with a view to strengthening his powers of requiring the safe keeping, record keeping, and packaging of "hard" and "soft" drugs. The representative bodies had fully endorsed the principle of his proposals for wider enabling powers to impose or modify controls as the situation developed. The detailed requirements would be discussed with the interests affected.

On the second proposed amendment he pointed out that the police had been hampered in detecting unauthorized possession by the present limits on their power to search on suspicion. The Government therefore proposed to give the police power to stop and search without warrant any person suspected of being in unlawful possession of a drug controlled under the 1964 and 1965 Acts. They intended to stop the "pushers" and pedlars of drugs by all means in their power.

Notification of Addicts

The Bill was an enabling measure, concerned solely with drugs scheduled under the Dangerous Drugs Act, 1965. It extended to Scotland and Northern Ireland. Under the powers it conferred the Home Secretary would be able to make regulations to require the notification of addicts by doctors and to prohibit doctors, except under licence, from providing addicts with specified drugs—initially heroin and cocaine. As regards notification the regulations would have to define addiction, state the circumstances in which notification would be required, specify the central authority (the Chief Medical Officer of the Home Department), and prescribe the procedure for notification. Lord Stonham emphasized that notification would have no legal consequences of any kind for the addict. It would not give the patient any continuing status as an addict as if he had been registered. The central records of notification would simply enable the inquiring doctor to be put in touch with any doctor who had previously notified that patient. Information provided by doctors would be safeguarded under the Official Secrets Act.

The intention was that in selected Health Service hospitals the doctors who received licences would be consultant psychiatrists in charge of the treatment of persons addicted to heroin and cocaine, and certain medical staff under their supervision. The criteria to be aplied for licensing doctors in approved centres outside the Health Service were under consideration.

Response of Hospitals

LORD SANDFORD, speaking for the Opposition, offered the opinion that doctors would come to regret their decision to do other than the Brain Committee had recommended and keep control of the disciplinary procedures, in this case by the General Medical Council. It was not a decision of the Government, or the wish of the Opposition, but a decision of the medical profession that would bring down on them all the paraphernalia of tribunals referred to in clauses 2 and 3 and in the schedule.

The object of the Bill was to shift the treatment of addicts into centres to be established, primarily in the London and Metropolitan hospitals. The Minister of Health had set out what he wanted of the hospitals in a memorandum of 7 March. What response had there been? His own information—admittedly incomplete—was that the hospitals were far from satisfied: they had been given no extra money; they were not clear how the centres were to operate; and they were far from ready to make the provisions without which the Bill could not operate.

(*Continued overleaf*)

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending **10 June** (No. 23) and corresponding week **1966**.

Figures of *cases* are for the countries shown and for Greater London. Figures of *deaths* and *births* are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES	1967					1966				
	Eng. & Wales	Gtr. Lnd	Scot.	N. Ire.	Eire	Eng. & Wales	Gtr. Lnd	Scot.	N. Ire.	Eire

* Measles not notifiaole in Scotland, whence returns are approximate. † Includes primary and influenzal pneumonia. § Includes puerperal pyrexia.

Established Machinery

Lord Amulree sought an assurance that the old machinery, such as it was, would not be taken away before the new machinery was ready; that the general practitioner would not be banned from prescribing drugs to addicts until the network of treatment centres was working properly; and that extra money would be found for the establishment of clinics and staff, and premises if necessary.

Lord Segal thought the most welcome part was the provision that regular prescribing of dangerous drugs should be taken out of the hands of the general practitioner and devolve on licensed consultants who would be able to keep a strict control over the patient. It was highly important that the element of financial gain to the general practitioner by his prescribing of dangerous drugs to an addict should be entirely removed.

Government's Reply to Debate

Lady Phillips, answering the debate for the Government, told Lord Sandford that the Minister of Health felt that the hospitals, after full discussion of the March memorandum, were "quite happy about the proposals," and that their response had, in fact, been most satisfactory. Additional funds needed by some teaching hospitals would be forthcoming. Some hospitals had particular problems, such as additional staff, and these were being examined.

Heroin was regarded as the best drug for some cases of intractable pain, and it was certain that the medical profession would not accept a prohibition on the prescription of heroin for the treatment of new patients.

She assured Lord Amulree that the old machinery would not be removed before the new was established.

All hospital boards were given additional money each year for development, and in general the Minister expected them to be able to finance the treatment centres from this money. It might be more difficult for the teaching hospitals, whose budgets were smaller than those of the regional boards, but the Minister had said that if necessary extra money would be made available from a small contingency fund.

The **Home Secretary** stated in answer to a question on 22 June that the Minister of Health and he hoped that the notification regulations under the Dangerous Drugs Bill could be brought into operation in the autumn and the prescribing regulations in the new year; but until consultations with the medical profession and other interests were further advanced he could not say when these regulations would be published.

Homosexual Law Reform Bill

Opponents of the Sexual Offences (No. 2) Bill marshalled their forces against its further progress on the report stage in the House of Commons on 23 June, and successfully prevented its being completed. According to the rules of the private members' legislation the Bill has now failed, since the time allotted to back-bench legislation has run out before it has completed its passage through the House. There appears to be some expectation among its supporters that the Government will come to their rescue by giving it additional time.

Questions in the Commons

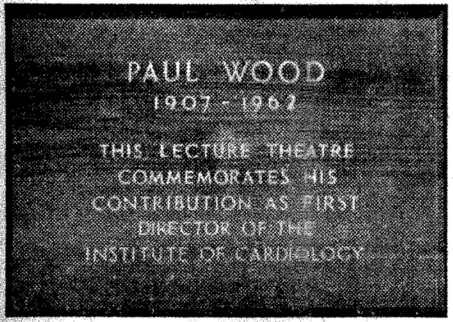
Health Check Weeks

Mr. **Julian Snow**, Parliamentary Secretary to the Ministry of Health, explaining the Ministry's attitude to health checks on 14 June, said that screening of the general public should be undertaken only for conditions that could be clearly and accurately diagnosed. Except in these circumstances it could do harm and was, in any case, a wasteful use of resources both local and national. For that reason he was not convinced on present evidence that this method of detecting disease should be recommended to health authorities generally. The Ministry, however, was most interested in the work that was being done by local authorities in this field and was following it closely.

Safety Order for Tractors

The Commons on 21 June approved an order requiring tractors to be fitted with a safety cab or frame. The regulations would apply to new tractors in three years' time. For used tractors bought before 1 September 1970 the obligation on farmers to provide cabs for them would not apply for a further seven years.

MEDICAL NEWS



Paul Wood Memorial Tablet

A plaque to the memory of Dr. **Paul Wood**, the first director of the Institute of Cardiology, was unveiled on 23 June by Sir **John McMichael**, F.R.S., director of the British Postgraduate Federation.

The ceremony was held in the Institute's lecture theatre at the National Heart Hospital in the presence of Mrs. Wood and members of the family. In his tribute Sir John referred to the great part Dr. Wood played in the development of the Institute and to the inspiring influence he had on his staff.

About 80 members of staff, past and present, attended the unveiling.

Appointments to Professorships

Dr. **Ian MacDonald**, reader in physiology at Guy's Hospital Medical School, has had the title of professor of applied physiology conferred on him in respect of his post at Guy's. Dr. Macdonald graduated at Guy's Hospital in 1944 and after holding several house appointments and serving in the R.A.M.C., mainly in the Middle East, he joined the physiology department at Guy's. He proceeded to the Ph.D. in 1953, and M.D. in 1959, and the D.Sc. in 1966. In 1958 he was a lecturer in physiology at the University of Witwatersrand and in 1961 a visiting research worker in the department of medicine, University of Cape Town, where he studied lipid metabolism in kwashiorkor. Dr. Macdonald has published several papers on the metabolic effects of dietary carbohydrates. He has served as a member of the council of the Nutrition Society.

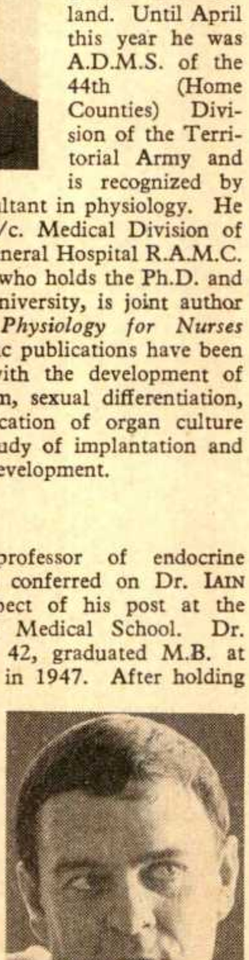
Dr. T. C. N. **Gibbens**, reader in forensic psychiatry at London University, has been appointed titular professor with effect from 1 October. Dr. Gibbens was educated at Westminster School, Emmanuel College, Cambridge, and St. Thomas's Hospital, and graduated in 1939. He served throughout the war in the R.A.M.C., from 1940 to 1945 in a P.O.W. hospital in Germany. After a year as house-physician at the Postgraduate Medical School at Hammersmith he became registrar at the Maudsley Hospital. From 1948 to 1950 he held a Nuffield fellowship in psychological medicine, and studied at the Institute of Psychiatry in New York and Sing-Sing prison psychiatric unit. On return to this country he became senior lecturer in forensic psychiatry and was appointed reader in 1964. During this period he was also psychiatrist to the L.C.C. remand home for girls, and served on the Streatfield Committee and on the Royal Commission on the penal

[Barr

system. He is a member of the Advisory Council for Probation and Aftercare, and of the research subcommittee of the Advisory Council on the Penal System. This year he is president of the British Academy of Forensic Sciences and of the International Society of Criminology. His publications include *Shoplifting* (1962), *Psychiatric Studies of Borstal Lads* (1963), and *Cultural Factors in Delinquency* (1966).

Dr. FRANCIS O'GRADY, reader in bacteriology at St. Bartholomew's Hospital, London, has had the title of professor of bacteriology conferred on him in respect of his post. Dr. O'Grady, who is 41, entered the Middlesex Hospital Medical School as a Scholar in 1945 and after obtaining first-class honours in the London Special B.Sc., Physiology, graduated M.B., B.S. with honours in 1950. After house - physician appointments at the Middlesex and North Middlesex Hospitals he began his career in pathology at the Bland-Sutton Institute. There he worked with the late F. R. SELBIE on experimental tuberculosis and hypersensitivity. He continued this work, with studies on the human tuberculin reaction, while pathologist to the Army Chest Centre, and this formed the basis of the thesis for which he was awarded the M.Sc. in 1956 and the M.D. in 1957. After the Army he returned to the Bland-Sutton Institute, where he worked on the pathogenesis and treatment of mouse thigh candidosis. In 1950 he was invited to join R. L. RILEY and the late W. F. WELLS in the experiment they were conducting in Baltimore to demonstrate the mechanism of airborne transmission of human pulmonary tuberculosis. The results of this and other epidemiological studies were embodied in a book with R. L. RILEY, *Airborne Infection: Transmission and Control* (see *B.M.J.*, 24 November, 1962, p. 1374). Relinquishing his appointment as assistant professor of environmental medicine at Johns Hopkins, he returned to this country, and in 1962 he was appointed to his present post, vacated by R. A. SHOOTER when he became head of the department. Dr. O'Grady's recent investigations have been into the mechanisms and management of urinary tract infection.

Dr. T. W. GLENISTER, vice-dean and reader in anatomy at Charing Cross Hospital Medical School, has had the title of professor of embryology conferred on him in respect of his post at the school. Dr. Glenister, who is 43, graduated from St. Bartholomew's Hospital Medical College in 1947. After house appointments at St. Bartholomew's Hospital and St. Andrew's Hospital, Dollis Hill, he served for two years in the R.A.M.C. In 1950 he was appointed demonstrator in anatomy at Charing Cross Hospital Medical School, where he was promoted lecturer in 1952, senior lecturer in 1954, and reader in anatomy in the University of London in 1957. In 1954 he was a member of the first international team undertaking embryological research at the Hubrecht Laboratory, Utrecht, and he visited various centres in the United States in 1963. He served as programme secretary and assistant secretary of the Anatomical Society of Great Britain and Ireland. Until April this year he was A.D.M.S. of the 44th (Home Counties) Division of the Territorial Army and is recognized by the Army as a consultant in physiology. He now serves as O. i/c. Medical Division of the 217 (Eastern) General Hospital R.A.M.C. (V). Dr. Glenister, who holds the Ph.D. and D.Sc. of London University, is joint author of *Anatomy and Physiology for Nurses* (1965). His scientific publications have been concerned mainly with the development of the urogenital system, sexual differentiation, and with the application of organ culture techniques to the study of implantation and early mammalian development.



The title of professor of endocrine chemistry has been conferred on Dr. IAIN MACINTYRE in respect of his post at the Royal Postgraduate Medical School. Dr. MacIntyre, who is 42, graduated M.B. at Glasgow University in 1947. After holding house appointments at Stobhill Hospital, Glasgow, and Peterborough Memorial Hospital he became assistant chemical pathologist at the Royal Hospital, Sheffield, and demonstrator in the university department of biochemistry under Professor Sir HANS KREBS. In 1952 he was appointed registrar in chemical pathology under Professor EARL J. KING at the then Postgraduate Medical School of London, and was awarded the first Drummond Fellowship in 1954. He became assistant lecturer in 1956, lecturer and consultant in 1959, and reader in 1963. He holds the Ph.D. and is a founder member of the College of Pathologists. Dr. MacIntyre was visiting scientist at the National Institutes of Health, Bethesda, Maryland, during 1961 and visiting professor of medicine in the University of California at San Francisco in 1964. He will be joint director with Professor RUSSELL FRASER of the new endocrine unit at the Royal Postgraduate Medical School. His published work includes papers on renal function, total body composition, magnesium metabolism, and on the origin, chemistry, and physiology of thyrocalcitonin.

Butterworth Gold Medal

The subject of this year's essay for the Royal College of General Practitioners' Gold Medal is "The Manifestations and Management of Senility," and for 1968 "The Promotion of Health After Leaving School." Essays for 1967 should be identified by motto only, with the author's name and address in a sealed envelope, and should not exceed 10,000 words. They should be submitted to the chairman of the awards committee, Royal College of General Practitioners, 14 Princes Gate, London S.W.7, by 31 August.

Royal College of General Practitioners

On 23 June Mr. DAVID BRUCE, the United States Ambassador, unveiled a plaque to the memory of President KENNEDY at the Royal College of General Practitioners, Hyde Park. Mr. Kennedy lived in the building when his father was Ambassador to Britain. Dr. ANNIS GILLIE, president of the College, and Dr. H. N. LEVITT, chairman of the Council, also participated in the ceremony. The unveiling was followed by a reception.

People in the News

▶ Dr. JOHN APLEY, lecturer in child health at Bristol University, is to succeed Dr. PHILIP EVANS as leader of the British paediatric team in Saigon (see *B.M.J.*, 2 July, 1966, p. 61).

▶ Dr. EDWARD COOPER, of the Chester Beatty Research Institute, London University, has been appointed head of the department of experimental pathology and cancer research at Leeds University.

▶ D. V. PARKE, Ph.D., reader in biochemistry at St. Mary's Hospital Medical School, London, has been appointed to the chair of biochemistry at the University of Surrey.

▶ Dr. TREVOR WESTON has been appointed editor for Family Doctor Publications.

Coming Events

West London Medico-Chirurgical Society.—Annual dinner, 6 July, 8 p.m. for 8.30 p.m., Mitre Hotel, Hampton Court. Tickets £2 2s. Applications to Honorary Secretaries, West London Medico-Chirurgical Society, West London Hospital, Hammersmith, London W.6.

King Edward's Hospital Fund for London.—Meeting on management services and information systems, 18 July, Hospital Centre, 24 Nutford Place, London W.1.

British Association for the Advancement of Science.—Annual meeting, 30 August to 6 September, Leeds.

Third Malaysian Congress of Medicine.—11–13 August, Kuala Lumpur. Details from the Secretary, Dr. S. T. PAI, Department of Surgery, University of Malaya, Pantai Valley, Kuala Lumpur, Malaysia.

Association des Médecins de Langue Française.—Congrès Français de Médecine, 26–30 September, Montreal. Details from Secretariat, 13 rue Molière, Paris 1.

Vth World Congress of Gynaecology and Obstetrics.—23–30 September 1967, Sydney. Details from Secretary-General, G.P.O. Box 4139, Sydney, Australia.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Monday, 3 July

Institute of Diseases of the Chest.—6.15 p.m., Dr. B. E. Andrews: The Virologist and Lung Disease.

Tuesday, 4 July

Institute of Dermatology.—4.30 p.m., Mr. R. R. Phillips: Uses and Methods of Photography in Dermatology.

London University.—At Charing Cross Hospital Medical School, 5 p.m., special university lecture in medicine by Professor D. W. Seldin (Texas): Pathogenesis and Treatment of Oedema.

St. Charles's Hospital Medical Centre.—8.45 p.m., clinicopathological conference: A Case of Diabetes with Complications.

West Suffolk Hospitals Postgraduate Centre.—At Drummond Hall, West Suffolk General Hospital, 1.15 p.m., Dr. J. Wedgwood: Use and Abuse of Antibiotics.

Wednesday, 5 July

Royal Free Hospital.—5.15 p.m., Dr. J. Waldenström (Malmo, Sweden): Disorders of Protein Metabolism.

Royal Postgraduate Medical School.—2 p.m., urology seminar. (2) 5 p.m., Professor J. Kirklin (Baltimore, U.S.A.): Problems of Interest in the Surgical Treatment of Acquired Valvular Heart Disease.

Stoke Mandeville Hospital.—(1) 12.15 p.m., Dr. M. S. Good: Clinical cases. (2) 6 p.m., Dr. M. Kinsbourne: Brain Stem Syndromes.

West Middlesex Hospital.—At Lecture Theatre, 5 p.m., postgraduate lecture by Dr. D. M. L. Doran: Gout.

Thursday, 6 July

Royal Postgraduate Medical School.—4 p.m., Mr. P. McKelvie: Laryngeal and Pharyngeal Neoplasms.

Friday, 7 July

Royal Postgraduate Medical School.—(1) 10.15 p.m., Mr. M. Hobsley: Influence of Acid/Base Balance on Gastric Secretion; (2) 11.30 a.m., Mr. A. Cox: Clinicopathological conference.

Sunday, 9 July

Clwyd and Deeside Board of Postgraduate Studies.—At Royal Alexandra Hospital, Rhyl, 10 a.m., symposium: Malignant Disease.

Royal Northern Hospital, London.—10 a.m., Dr. D. Geraint James: clinical conference.

New Issues of Specialist Journals

Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London W.C.1.

ANNALS OF THE RHEUMATIC DISEASES

Contents of the May issue are as follows:

Heberden Oration, 1966: Categorization of Medicine: A Survey of Still's Disease. E. G. L. Bywaters.
The Joint Disease of Sarcoidosis. J. M. Gumpel, C. J. Johns, and L. E. Shulman.
Fibrin Promotion and Lysis in Arthritic Joints. M. I. Barnhart, J. M. Riddle, G. B. Bluhm, and C. Quintana.
Significance of the Occurrence of Transparent Skin: A Study of Histological Characteristics and Biosynthesis of Dermal Collagen. B. McConkey, K. W. Walton, S. A. Carney, J. C. Lawrence, and C. R. Ricketts
Carpal Tunnel Syndrome in Rheumatoid Arthritis. C. G. Barnes and H. L. F. Currey.
Relative Roles of Genetic and Environmental Factors in the Control of Serum Uric Acid Levels in Normouricaemic Subjects. J. A. Boyle, W. R. Greig, M. K. Jasani, A. Duncan, M. Diver, and W. Watson Buchanan
Jaccoud's Arthritis. E. Beausang, E. V. Barnett, and S. Goldstein.
Phenolsulphonphthalein Clearance from the Knee Joint in Normal and Pathological States. R. Nakamura, H. Asai, H. Sonozaki, and M. Nagano.
Ferritin Formation by Synovial Cells Exposed to Haemoglobin in vitro. K. D. Muirden, J. R. E. Fraser, and B. Clarris.
Topical Fluocinolone in Rheumatoid Arthritis. L. Hall and the late N. R. Banerjee.
Heberden Society. Book Review. New Zealand Rheumatism Association. Abstracts.

Volume 26, No. 3. Yearly subscription (6 numbers) £4 4s., abroad £4 15s.

BRITISH JOURNAL OF OPHTHALMOLOGY

Contents of the June issue are as follows:

Retinal Vasculitis Associated with Anterior Uveitis. J. Nolan and J. F. Cullen.
Volume Changes in Indentation Tonometry. U. Majzoub.
Retrocorneal Membranes. I. Their Origin and Structure. E. S. Sherrard and P. V. Rycroft.
Retrocorneal Membranes. II. Factors Influencing Their Growth. S. S. Sherrard and P. V. Rycroft.
Vascular Abnormalities in Disciform Degeneration of the Macula Lutea Demonstrated with Fluorescein. L. Lemke and A. Jütte.
Effects of Prednisolone Eye Drops. T. G. Ramsell, W. Trillwood, and G. Draper.
Fibromyxosarcoma of the Eyelid. I. M. Shukla and S. Agrawal.
Invasion of the Orbit by Maggots. S. P. Mathur and J. M. Makhija.
Microsurgery in Ophthalmology. M. J. Roper-Hall.
A Simple Cryosurgical Instrument and its Application in Ethiopia. J. Edwards, L. L. Woodget, F. O. Mueller, and R. Ludek.
A Sterile Disposable Cryoextractor (Cryophake). Jack W. Passmore and Robert P. Hughes.
New Iris Retractor for Use in Cryosurgery. G. M. Maclure.
Ophthalmological Synopses. Review. Obituary. Notes.

Volume 51, No. 6. Yearly subscription (12 numbers) inland £8 8s., overseas £9. With *Ophthalmic Literature* and Index (7 numbers) inland £15, overseas £16.

BRITISH JOURNAL OF MEDICAL EDUCATION

Contents of the June issue are as follows:

List of Contributors.
Editorial.
Educational Science and Education for Medicine. George E. Miller.
Individual Study and Educational Technology. C. E. Engel.
Programmed Instruction in Medical Education: Comparison of Teaching-machine and Programmed Textbook. T. B. Stretton, R. Hall, and S. G. Owen.
Medical Students' Sudy: Time and Place. Nicolas Malleson.
The Students' Health and Welfare Centre (SHAWCO), University of Cape Town, South Africa. David Katz.
Neglected Fundamentals in Undergraduate Psychiatric Education. A. C. Woodmansey.
Role of Genetics in Medical Education in North America. R. J. F. Withers.
Marking Multiple-choice Examinations. Bernard Lennox.
Guessing in Multiple-choice Tests. B. Cooper and J. M. Foy.
Closed-circuit Television and Videotape Recording in Teaching Pharmacology. J. D. Gasking, J. P. Quilliam, and K. E. Wiggins.
Projectors. N. C. Manley-Cooper.
Medical Research Council Support for the Training of Research Workers. Joan Faulkner.
Book Reviews. News and Notices.

Volume 1, No. 3. Yearly subscription (4 numbers) £3 3s., abroad £3 10s.

Universities and Colleges

CAMBRIDGE

Appointment.—Dr. M. J. Mitchinson (university lecturer, pathology).

The M.D. Committee have awarded the Raymond Horton-Smith prize for 1965–6 to Dr. G. R. Fraser for a thesis entitled The Causes of Blindness in Childhood.

The M.D. Committee have awarded the Sir Lionel Whitby medal for 1965–6 to Dr. D. A. Hopkinson for a thesis on Genetical and Biochemical Studies on Human Red Cell Acid Phosphatase in Health and Disease.

M.D.—D. A. Chamberlain, A. M. Fisher, J. E. Stark, P. J. Crosland-Taylor, R. E. Kendell, R. Carlisle, L. J. Chalstrey.

M.Chir.—*E. C. Ashby, *R. H. Whitaker, H. B. Stallard, M. Spiro, D. E. Elgar.

M.B.—P. J. Black, *C. B. Bentley Phillips, M. A. Hutson, P. E. M. Jarrett, Cecilia A. Lindsay-MacDougall.

* By proxy.

ABERDEEN

Appointments.—Dr. N. Edwood (lecturer, medicine); Dr. C. Murray (chief medical officer, Student Health Service); Dr. C. H. Baxter (terminable lecturer, chemical pathology); Dr. P. N. Bennett (terminable lecturer, medicine); Dr. J. S. Legge, Dr. R. F. Scott (terminable lecturers, pathology); Dr. P. A. Slater, Dr. Julie C. Carter (lecturers, pathology).

EDINBURGH

Appointments.—Dr. D. W. Straughan (senior lecturer, Department of Pharmacology); Dr. Catherine M. U. Maclean (lecturer, Department of Social Medicine); Dr. Elizabeth Fender (lecturer, Department of Anatomy); Dr. A. G. Fraser (lecturer, Department of Bacteriology); Dr. H. J. K. Mamattah (temporary lecturer, Department of Bacteriology).

BIRMINGHAM

Appointments.—Dr. J. M. Wilson (research fellow, Department of Theology); Dr. G. Harris (lecturer, Department of Experimental Pathology); Dr. M. J. Andrews, Dr. J. E. D. MacLaren, Dr. M. J. McMahon (temporary lecturers, Department of Anatomy).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council held on 8 June, with Professor (now Sir) Hedley Atkins in the chair, the Sir Arthur Keith medal was presented to Professor A. J. Harding Rains.

The Begley prize was presented to Dr. R. A. Lucas (St. Mary's Hospital).

Professor R. B. Duthie, the Nuffield professor of orthopaedic surgery, Oxford, was elected to the Fellowship *ad eundem*.

The following were co-opted to the council for the year 1967–8, representing various branches of practice: Anaesthetics, Dr. Derek Wylie; Dental Surgery, Mr. Terence Ward (re-election); General Practice, Dr. A. J. Whitaker; Gynaecology and Obstetrics, Mr. J. A. Stallworthy (re-election); Ophthalmology, Mr. A. G. Cross (re-election); Otolaryngology, Mr. D. Ranger; Radiology, Dr Thomas Lodge (re-election).

A diploma of membership was granted to D. E. MacFarlane.

After the meeting the Gordon-Taylor lecture was delivered by Sir Eric Riches, on "The Gordon-Taylor Tradition in the Surgery of Cancer."

All communications with regard to editorial business should be addressed to The Editor, British Medical Journal, B.M.A. House, Tavistock Square, London W.C.1. Telephone: 01-387 4499. Telegrams: *Aitiology, London W.C.1.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

ADVERTISEMENT AND SUBSCRIPTION ORDERS should be addressed to The Manager at B.M.A. House, London, or at 415 Bourke Street, Melbourne, Victoria, Australia.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A., Scottish Office, Drumsheugh Gardens, Edinburgh.

Pointers

Post-concussional Sequelae: Patients may have organic lesions in the brain which are as yet insufficiently studied, according to Mr. A. R. Taylor (p. 67). Leader this page.

Significance of Systolic Clicks: Dr. Mary Stannard and colleagues, from Melbourne, Australia, confirmed prolapse of posterior leaflet of mitral valve and the incidence was familial in 13 patients (p. 71).

New Semisynthetic Penicillin: Carbenicillin reported active agent against *Ps. pyocyanea* by Dr. E. T. Knudsen and colleagues (p. 75). Drs. R. J. Jones and E. J. L. Lowbury found that combined with gentamicin it protected burned mice against *Ps. aeruginosa* (p. 78).

Urinary White Cell Excretion: Dr. R. M. Lindsay and colleagues found significant rise in females but not in males after surgery (p. 83).

Convulsive Status Epilepticus: Drs. M. J. Parsonage and J. W. Norris used intravenous diazepam for effective control (p. 85). Leader at p. 63.

Intermittent Haemodialysis: Mr. G. J. A. Clunie and colleagues describe satisfactory experiences with Silastic-Teflon arteriovenous cannula system (p. 88).

Prevention of Urinary Infection: Professor W. A. Gillespie and colleagues report use of sterile disposable plastic drainage bags satisfactory for closed drainage (p. 90).

Case Reports: Methaqualone addiction and delirium tremens (p. 92). Successful treatment of thrombocytopenic purpura (p. 93).

Today's Drugs: Radioiodine therapy (p. 95).

New Look at Postgraduate Training: Mr. P. W. R. M. Alberti advocates formal postgraduate training programmes to replace present haphazard schemes (p. 101).

Accidents in Childhood: A memorandum of the British Paediatric Association (p. 103).

Research in Progress: M.R.C. Rheumatism Research Unit (p. 105).

Contact Lenses: Description of suction holder (p. 106).

Pertinax: Without Prejudice (p. 107).

Common Market and Medicine: Letter from Italy (p. 108).

Proceedings of Council: Approval given to reorganization of representative machinery for hospital junior staff, *Supplement,* p. 15.

G.M.S. Committee: Dr. J. C. Cameron reelected chairman and negotiating team appointed, *Supplement,* p. 18.

Post-concussional Syndrome

The pathogenesis and management of the sequelae of closed head injury have been matters of dispute for more than a century. As Mr. A. R. Taylor points out in his paper at page 67 of the *B.M.J.* this week, there are two principal schools of thought on the aetiology of the post-concussional syndrome: some believe that symptoms after even minor head injury are the result of physical damage to the brain, while others equally firmly hold the view that the symptoms are mostly of psychogenic origin.

In his review of concussion, written in 1962, Sir Charles Symonds[1] stressed the pathological and experimental evidence that damage to neurones and white matter was a common sequel of closed head injury, and he favoured the organic view. But in 1966 Henry Miller,[2] after analysing his experience of many cases referred to him in connexion with claims for compensation, found it difficult to believe that the clinical features of this disorder could justify its speculative attribution to cellular damage. Now as evidence in support of the organic origin of post-concussional symptoms Taylor points out that in various conditions headaches, dizziness, lack of energy, and defects of memory and concentration may result from brain damage even when there are no accompanying physical signs. He refers to evidence[3] showing that the brain may be more severely damaged from a relatively minor blow to the head if the head is freely movable than by a blow severe enough to fracture the skull with the head immovable. While it is true that professional men often return to work more quickly after a head injury than do manual workers, many who did so within six months still had symptoms 18 months after the injury. Mr. Taylor incidentally mentions three doctors who suffered disabling symptoms long after injuries for which no compensation was claimed. Surveys of German soldiers suffering head injury in the first world war[4] and a study of Americans after the Korean war[5] showed that many had significant and persistent symptoms and had not been able to return to satisfactory employment. There is also neuropathological evidence that damage to axons and myelin sheaths and to nerve cells in the brain-stem and in the cerebral hemispheres may follow relatively minor injury, while special tests[6 7] have shown disorders of vestibular function and persisting, posturally induced nystagmus in many patients.

For these reasons Taylor discards the view that patients with head injury, if properly managed, socially adjusted, and carefully rehabilitated, will not have "neurotic symptoms." He suggests that minor difficulties in concentration and performance indicate that these people have suffered organic cerebral damage. Many of these patients are abnormally sensitive to alcohol and some undergo lasting changes of personality.

At first sight these arguments seem, as Taylor points out, to refute Miller's[8] conclusion that the severity and duration of post-concussional symptoms are inversely proportional to the severity of the head injury. In a clinical situation where exact methods of examination and investigation are rarely informative and in which pathological evidence is relatively

© British Medical Journal, 1967. All reproduction rights reserved.

scanty, opinions are bound to differ. However, it seems that in many respects Taylor and Miller are describing different syndromes. Most neurologists and neurosurgeons would accept that frontal and occipital headaches which are present on waking, throbbing in character, and accentuated by bending or coughing or sneezing are usually organically determined. Most would also accept that disorders of memory and concentration and transient vertigo ("dizzy bouts," with transitory staggering brought on often by change in posture) are common results of organic damage after closed head injury. Like post-traumatic epilepsy, commonly appearing in 6 to 18 months after a head injury sufficient to give post-traumatic amnesia of 24 hours or more, these symptoms must surely be accepted as organic. They may resolve slowly, but generally do so in the less severely injured patients in one to two years after the accident. By contrast, any neurologist who frequently examines patients for medico-legal purposes is familiar with the type of injury which has produced no more than a minor laceration of the scalp without impairment of consciousness, an injury which if experienced in a domestic environment or on a field of sport would have been forgotten within a few days of the wound's healing, but which has been followed by apparently prolonged and disabling sequelae. Such patients often complain of "terrible" or "severe" headache which is vertical in situation or described as like a tight band, a weight, or sense of pressure. These symptoms are characteristic of non-organic headache and are common also in anxious or depressed patients who have never experienced head injury. Many symptoms may be associated with headache, but the physician often finds a striking over-reaction during the examination, which is punctuated by sighs, groans, and protestations of pain, and voluntary contraction of the muscles of the neck often impairs passive movement of the head. No neurologist of experience will accept that this syndrome, whether attributed to "hysteria" or to malingering, could have an organic basis. One difficulty is to assess the apparently intense depression, tension, and anxiety often seen in such cases. There are certainly patients in whom lasting phobias, related perhaps to the place of work where the accident occurred, to working at heights, or to riding in motor vehicles, are seen. The fact that symptoms often clear up in a few months after settlement of a compensation claim certainly supports Miller's thesis[8] about the nature of this type of traumatic or "compensation" neurosis. The same may be true of some "blackouts." Attacks like those described by L. D. Osler and M. G. Fusillo[9] as "a peculiar type of post-concussive blackout" may follow head injury, fail to respond to anticonvulsant therapy, yet cease abruptly after a substantial financial settlement.

Thus it is difficult to draw any firm conclusions about the aetiology and management of the post-concussional syndrome. Morning headache of throbbing character accentuated by movement, and vertigo induced by change in posture, together with disturbance of memory and concentration, are common and undoubtedly organic sequelae of closed head injury. Occasionally they follow minor trauma. The most that can be done in these cases is to advise adequate rest and relaxation, to give symptomatic treatment, and to reassure the patient that almost certainly the symptoms will eventually resolve. But when florid neurotic or "hysterical" manifestations follow trivial head injury, early settlement of any outstanding compensation claim is the single most significant factor contributing to ultimate recovery.

Asbestosis

The first case of asbestosis was described as "typical fibroid phthisis" by H. M. Murray in 1907,[1] but it was another 20 years before there was an official inquiry into conditions in asbestos factories.[2] Soon afterwards W. B. Wood and S. R. Gloyne[3] thought that the disease was getting under control, a view shared 15 years later by H. Wyers.[4] These authors were concerned only with asbestos processing and textile manufacture and their optimistic statements have not withstood the test of time and of the expanding use of asbestos. It is true that in those factories where the asbestos regulations of 1931[5] have been rigorously implemented the excess mortality has been considerably reduced,[6 7] but on a national scale annual "certifications" for asbestosis have been rising since 1950.[8]

Asbestos has been used for at least 4,000 years,[9] but it became an important industrial mineral only at the end of the last century. Since then its output has risen from about 500 tons to more than 3 million tons per annum.[10 11] It has innumerable uses in building, shipbuilding, insulating, refrigeration, paper, textile, engineering, plastics, and many other industries. At present tests are being made with asbestos–asphalt for road surfacing.[12 13] The labour force in many of these industries is highly mobile and distributed over a large number of small units. In addition there is a vast number of "do it yourself" enthusiasts who may be exposed intermittently to highly concentrated asbestos dust. The biological significance of pulmonary asbestos bodies is not yet clear,[14] but they have been found in large proportions of necropsies in widely separated areas.[15 16]

Preventive measures and legislation have lagged behind clinical and pathological evidence. The rising numbers of certifications for asbestosis contrast strongly with the declining trends of most other mineral dust pneumoconioses. Part of the increase is certainly due to a lower threshold of suspicion and more accurate diagnosis. Probably many cases of asbestosis were in the past classified as idiopathic pulmonary fibrosis, bronchitis, or Hamman–Rich syndrome. Significantly, not less than 58% of 315 newly diagnosed cases of asbestosis were found in unscheduled occupations such as laggers, brakeliners, and sprayers.[14]

The pulmonary fibrosis caused by asbestos is a disabling condition, but unlike disease produced by exposure to silica and coal dust asbestosis also carries a serious risk of malignant neoplasia of the bronchus and of the serous membranes, and possibly also of carcinoma of the gastrointestinal tract.[17]

The association between asbestosis and lung cancer was first described by K. M. Lynch and W. A. Smith in 1935,[18] and has since been confirmed by many investigators. The

Chief Inspector of Factories stressed the association in 1947[19] and R. S. Doll and his colleagues have published follow-up and cohort investigations[20 21] which suggest that in at least one factory the attack rates from bronchogenic cancer in men who entered the industry after 1933 are not higher than would be expected in the general population. But in the United States E. C. Hammond and his colleagues[22] reported 53 deaths from lung cancer in 300 consecutive necropsies of insulating workers, and found the death rates from pulmonary and pleural cancers seven times higher in asbestos workers than in American white males.

Since J. C. Wagner and his colleagues[23] first described the occurrence of pleural mesotheliomata in the crocidolite mining districts of South Africa many cases have come to light elsewhere. In Britain most cases have been discovered in London[24] and at the larger ports where much asbestos is handled in the shipbuilding industry.[12 25 26] Diffuse peritoneal tumours associated with asbestos exposure have been reported.[27] There seems to be little doubt that these tumours—which as recently as 1960 were regarded as " rare curiosities "[28]—are of occupational or environmental origin. Wagner[29 30] produced pleural neoplasms in animal experiments, and his findings have now been confirmed by other investigators.[31] The important question of whether only crocidolite or other types of fibres also, especially the widely used chrysolite, have carcinogenic properties has not yet been unequivocally answered.[14]

Two aspects of the asbestos–mesothelioma association are very disturbing. In some cases extremely short exposures have been reported.[12 24] There is also growing evidence that residents in asbestos mining or manufacturing districts and those at risk by the brushing and washing of contaminated working clothes can develop mesenchymal tumours or the bizarre pleural fibrosis and calcifications which seem to be associated with exposure to asbestos.[32 33]

The scope of the problems yet to be solved has been clearly set out by J. C. Gilson in his summing up of a symposium held in New York[34] and in the report of the subcommittee of the International Union against Cancer.[35] The most important of these problems are: the type of asbestos as a factor in the risk of asbestosis and malignancy; the excess risk of malignancy from asbestos in the absence of clinical, physiological, and radiological manifestations of asbestosis; the organization of prospective surveys to establish the risk to industrial and residential populations; agreement on the clinical, lung function, and the notoriously difficult radiological criteria for diagnosing asbestosis; agreement on the most accurate type of dust measurements; and the clinical significance of pleural plaques and of asbestos bodies.

In the meantime it is to be hoped that the promised revision of the 1931 Asbestos Regulations[36] will soon be put into effect and that they will cover all workers at risk, including those engaged in loading and transporting asbestos. Present evidence suggests that crocidolite is the most dangerous of asbestos fibres and it may be possible to find suitable substitutes for at least some of its uses. The uncontrolled dumping of asbestos waste[37] should not occur again. Finally, in view of the long induction period of asbestosis and malignancy the present restriction, that a worker claiming disability benefits for mesothelioma under the Industrial Injuries Act must have been employed after 4 July 1948,[38] seems to be entirely unrealistic and should be abolished.

Status Epilepticus: A Medical Emergency

Despite modern treatment status epilepticus remains a dangerous condition carrying a high mortality. Its consequences remain largely uncharted because in most instances reports of treatment end with the control of the status or death. But, since there is evidence that the longer the status continues the greater the mortality, early treatment is important and status should be regarded as a medical emergency.

Status epilepticus is defined as the occurrence of grand mal convulsions without recovery of consciousness between fits. The recognition of fully developed status is easy enough: not only have fits been multiple and usually frequent, with persisting unconsciousness, but other signs of physiological stress —in the heart, lungs, kidneys, and in fluid and electrolyte balance—may have developed. A practical problem is to decide at what stage the patient needs transfer to hospital and to the sometimes very specialized management that may be required. Many patients in early status respond rapidly to a simple increase in the routine anticonvulsants they are already having. Moreover, when status supervenes in an established case of epilepsy there is often adequate warning in the form of increased frequency of fits, up to several a day, but with recovery of consciousness between—so-called serial epilepsy. In these circumstances a trial may be justified for a few hours—but no more—of the sort of measures that can be undertaken at home (paraldehyde intramuscularly in adequate dosage being a stand-by). But if status continues then admission to hospital should be arranged at once. When status occurs as the very first manifestation of epilepsy, as is not very uncommon when the causative focus is in the frontal region, the likelihood of an intractable form is much greater, and admission to hospital should certainly be arranged.

In established status the problem of management is threefold: to control the fits, to ensure an adequate airway and oxygenation, and to maintain the biochemical *milieu intérieur* as normal as possible. Monitoring of fluid balance, electrolytes, blood urea, blood pressure, and pulse will be required, and a simple airway may be needed. If status is long continued then tracheostomy with full curarization and assisted respiration may be necessary; in that case monitoring of blood $P\text{co}_2$ and $P\text{o}_2$ will also be called for. In some cases these measures are life-saving, and this makes the condition a matter for urgent admission to hospital.

The linchpin of treatment must remain the control of the fits, and the sooner this is achieved the less need there will be for other measures. If a substantial increase in routine anticonvulsants—given by injection rather than by mouth—does not abolish fits and allow return of consciousness within an hour or two, additional drugs must be used. The remedy most widely advocated is paraldehyde given intramuscularly or intravenously in glucose saline or plasma drip. The wide margin between anticonvulsant and serious toxic doses makes this a drug of choice. Other preparations—soluble barbiturates, soluble phenytoin, and inhalation anaesthetics—have been successfully used, but have not in general displaced paraldehyde. Recently, however, a new drug diazepam (Valium), introduced initially as a muscle relaxant and tranquillizer, has been found to give benefit in status. First reports on it came from French neurologists.[1] [2] Now Drs. M. J. Parsonage and J. W. Norris in this issue of the *B.M.J.* (page 85) give their experience of its use in nine cases of severe status. They gave it intravenously and in seven patients attained immediate control of seizures. The effect was rapid and obvious both on clinical seizures and on electroencephalographic discharges. Although in seven cases other methods of treatment were also used—including paraldehyde in four—there was no doubt that diazepam was a valuable and at times decisive therapeutic agent. Its rapidity of action and its absence of serious toxic effects must recommend it as one first choice in the treatment of persisting status. Initially it should be given intravenously, and Parsonage and Norris advise a saline drip (100 mg. per 500 ml.), though 10-mg. intravenous doses repeated may be given. Control may later be maintained by intramuscular injection. Once control is established a gradual return to the usual oral remedies should be undertaken. There is not yet any clear evidence that the drug is effective by mouth on its own, though it appears at times to be an effective adjuvant to others.

The addition of diazepam to the treatment of status does not reduce the seriousness of this condition. Parsonage and Norris's series contains two deaths, one patient with persisting severe dementia and one with residual hemiparesis. This morbidity is important and has been little considered heretofore. There is growing evidence that mental and neurological deficit may follow status. This reinforces the argument for rapid control of the condition, for careful attention to the biochemical milieu while it lasts, and for early and if possible preventive treatment.

Safer Dental Anaesthesia

In July 1965 the Standing Medical and Dental Advisory Committees of the Central Health Services Council set up a Joint Subcommittee at the request of the Minister of Health with the following terms of reference:

> To consider the use of general anaesthetics in general dental practice and to advise:
>
> (1) How far the administration of general anaesthetics for conservative treatment can be justified, and
>
> (2) How far the administration of general anaesthetics for any purpose without the attendance of a second practitioner can be justified.

This report has now been published[1] and the members of the Joint Subcommittee must be congratulated on producing a document which not only will influence the future of dental anaesthesia but will also serve as a model of the way to present authoritative and exact information in a concise form.

The report classifies the main groups of patients whose clinical condition may justify general anaesthesia for conservative work in general dental practice as follows: (*a*) spastics or others who because of physical infirmity would be uncontrollable under local analgesia; (*b*) patients who are known to react adversely or to be resistant to local analgesics; (*c*) mentally subnormal patients; (*d*) those whose psychological attitude to dentistry is such that they would refuse from fear any form of dental treatment not performed under anaesthesia and who, in the opinion of the dental surgeon, are unsuitable for local analgesia. It can be inferred from the report that the Joint Subcommittee thought some dental practitioners were making too little use of local analgesia for conservative dentistry, for the introduction of lignocaine as an analgesic agent nearly twenty years ago has made the employment of local analgesia reliable and certain. For many years the average Briton had an ingrained fear of the dental surgeon and did not consult him until he could request him to take all his teeth out "with gas but not cocaine." Little wonder then that he prefers that such conservative dentistry as he will permit should be performed while he is asleep. In other countries, such as the U.S.A. and Scandinavia, where local analgesia has been the routine form of pain relief for all types of dental surgery, the use of general anaesthesia for conservative dentistry has not been so enthusiastically championed as in Great Britain.

The report is careful to point out that the relatively low mortality connected with dental anaesthesia in the past is related to the short time for which it is administered. However, if longer operations become more frequent, the mortality and morbidity must inevitably rise, especially if practitioners who are not properly trained administer general anaesthetics for them. The report states that the "administration of general anaesthesia and the performance of dental surgery require the undivided attention of anaesthetist and operator respectively and . . . cannot be combined without risk." This authoritative statement will surely receive general assent.

---

[1] *Dental Anaesthesia,* Report of a Joint Subcommittee of the Standing Medical and Dental Advisory Committees on Dental Anaesthesia. Ministry of Health. 1967. H.M.S.O.

[2] *Brit. med. J.*, 1967, 1, 447.

Indeed, when sending the report to hospitals the Ministry states in an accompanying circular, "When an anaesthetic for dental treatment is administered to a patient in hospital, it is important that there should be one person with a clearly defined responsibility for the patient's general condition and general health whilst in hospital." Clearly this implies that the anaesthetist is responsible both for the preoperative assessment of the patient and for immediate postoperative care and that this is a responsibility which cannot be delegated to the less skilled. There can be no doubt that when a patient is rendered unconscious for a considerable time it is in the interests of his safety for the same criteria to be followed even though the operative work is done as an outpatient either in hospital or in general practice. The report concedes that there would not be enough trained anaesthetists to make this possible in every case, but the section discussing undergraduate and postgraduate teaching of both medical and dental students is comprehensive and will give much food for thought to those concerned with this problem. In all, this report points the way to safer and better dental anaesthesia, some aspects of which were recently discussed in these columns,[2] and it should encourage the development of this branch of the specialty of anaesthesia.

A Year's Cancer Research

The Forty-fourth Annual Report of the British Empire Cancer Campaign for Research was published this week.[1] It is shorter than its immediate predecessors as a result of a decision to exclude accounts of incomplete or inconclusive work. The provision of author and subject indices is an improvement, though the latter is less valuable than the summary which introduced the report in previous years.

The first stage of cancer research is to define the problem, and this is the role both of cancer registries, such as those in Kampala, Jamaica, Fiji, and Neyyoor in South India, and of the special panels concerned with tumours of the testis, bone, and thymus. Some of the difficulties of this first stage are evident in the report from Neyyoor, where religious and health beliefs, shortages of pathologists, and language differences make it difficult to obtain a clear idea of the incidence of the disease. Nearer home epidemiological data are somewhat easier to obtain, and the calculation of death rates for cancers and other diseases for Scotland, Northern Ireland, and Eire will provide valuable basic information for future work. New tables produced by R. A. M. Case enable the calculation of the risk of cancer at particular sites during the period 1911–1960 in these countries.

Circumstantial evidence favouring a virus as the cause of Burkitt's lymphoma continues to accumulate, but direct proof remains elusive. Meanwhile a national survey of tumours of domestic animals in England has shown, as expected, a relatively high incidence of leukaemia in cattle, and efforts are being made to find a virus cause for both this disease and the lymphosarcoma of cats and dogs. Attempts to recover the mouse sarcoma virus from tumours induced by it in the hamster were unsuccessful, though Huebner and his colleagues are reported to have succeeded in doing so by growing the hamster tumour cells in vitro in the presence of a murine leukaemic virus. According to Professor M. G. P. Stoker the Kilham rat virus, an osteolytic virus isolated from transplanted tumours, is the first animal virus found to contain single-stranded D.N.A. An interesting observation is that the Friend virus depresses the immune response in mice; a similar effect has been observed in response to mouse thymic virus and to treatment with chemical carcinogens.

Under certain conditions immune reactivity may be enhanced by prior exposure to *x*-radiation. From Newcastle upon Tyne C. A. H. Trench, C. A. Green, and others report an increased response to sheep erythrocytes in both rabbits and rats irradiated two months earlier. This may be relevant to treatment of cancer by radiotherapy. In relation to causation, however, V. Wallis and P. C. Koller conclude that in mice there is no obvious relation between the level of immune responsiveness after radiation and the subsequent development of leukaemia.

A peculiar and apparently specific affinity between submesothelial tissues and asbestos is reported by F. J. C. Roe and his colleagues at the Institute of Cancer Research. This may explain the causal relationship between exposure to asbestos and mesothelioma. The relative risk of different types of asbestos remains uncertain, but it is of interest that A. and P. R. Peacock have seen malignant tumours in fowls at the site of injection of tremolite as well as of amosite and crocidolite. According to J. S. Harington and G. Macnab asbestos may be present in phagocytes both in phagosomes and free in the cytoplasm. In Belfast, where asbestos cancer occurs in relatively high incidence, the department of therapeutics of Queen's University organized a meeting of medical officers from the Northern Ireland Ministry of Health and Social Services, from the Medical Research Council, and from several large industrial firms, which resulted in a general agreement to abide by the "Code of Practice in Handling Asbestos" drawn up by the Asbestosis Research Council.[2]

It is tragically true that many elegant and sometimes costly diagnostic techniques reveal cancers for which no more than palliative treatment is likely to be available. Of particular interest, however, is the localization of tumours by various isotope techniques. Like previous years, 1966 did not see the introduction of an automated system for the examination of cervical smears, but the development by A. I. Spriggs and M. M. Boddington of a technique for collecting and fixing cervical cells in suspension so that the cells can subsequently be stuck on to plastic tape for automatic scanning may be an important step forward. Similarly, the formation of a library of classified cervical cells should prove invaluable in the development of an automatic cell-recognition device. In view of the known association between poor sexual hygiene and the risk of cancer of the cervix uteri, it is perhaps surprising that more attention has not been paid to women attending venereal-disease clinics. In a survey of patients attending such a clinic H. C. McLaren and his colleagues in Birmingham found precancerous lesions in a number of women under 30 and in two under 20 years of age. Several groups of workers have persisted in their search for a suitable biochemical screening test for cervical precancer. In this connexion it is difficult to believe that any further study of the enzyme 6-phosphogluconate dehydrogenase is justified, since in no case has a rise in its level proved as reliable a guide as cytological investigation. According to G. G. Muir the level of the enzyme reflects an inflammatory reaction rather than the presence of malignant cells.

A method for predicting which form of endocrine ablation or hormone therapy is most appropriate to individual cases of breast cancer would constitute an important step forward. Unfortunately none of the many attempts to develop such a method has so far proved successful. Meanwhile A. P. M. Forrest and Helen J. Stewart express doubt whether pituitary implantation of yttrium-90 can always completely ablate the gland's function. A recent comparison of the results of different methods of treating carcinoma of the prostate[2] came to the disappointing conclusion that treatment with oestrogen did not result in a prolongation of life; in fact death from heart disease and cerebrovascular accidents was substantially more frequent in patients given 5 mg. oestrogen daily. Several centres are moving towards the use of computers in relation to radiotherapy dosimetry, while T. J. Deeley and M. A. Longy at the Hammersmith Hospital are working out methods for using computers in relation to the follow-up of cancer patients and assessment of treatment.

All those who helped the central organization and the three autonomous councils of the British Empire Cancer Campaign for Research to collect the record sum of £2m. deserve the highest praise, particularly as this has enabled the Campaign for the first time to guarantee its grants to major research centres for three consecutive years.

Intestinal Necrosis due to Digitalis

If digitalis had been introduced at the present time it is doubtful whether it would have passed the scrutiny of the Dunlop Committee. In spite of its immense value, the gap between therapeutic and toxic actions is narrow, especially in patients with chronic heart failure, in elderly patients, and when diuretics are given at the same time. Arrhythmias, such as ventricular extrasystoles and atrial tachycardia, are well-known indications of toxicity, and sudden death may result from cardiac arrest or ventricular fibrillation. J. L. C. Dall[1] has drawn attention to the dangerous situation in which refractory cardiac failure may be the result of treatment with digitalis. Various neuropsychiatric manifestations are easily overlooked, especially in the elderly; they include disturbances of vision, confusion, hallucinations, and depression.

Gastrointestinal symptoms are common. Anorexia, nausea, vomiting, and diarrhoea are well known, but the occurrence of abdominal pain is not sufficiently stressed, and its true nature may be mistaken for an intra-abdominal catastrophe. In some patients a syndrome of abdominal pain, diarrhoea, and melaena mimicking mesenteric occlusion has been attributed to digitalis.[2 3] In a recent report[4] three patients were encountered in a single year, and a further eight were discovered by reviewing post mortem records. All were elderly and had been taking digitalis for chronic heart failure. Many already had features of digitalis toxicity when they developed signs of ileus, with a tender, distended abdomen, coffee-ground vomiting, and melaena. The condition was invariably fatal within a few days of onset, and necropsy showed diffuse, haemorrhagic lesions throughout the mucosa of the stomach and intestines, most marked in the jejunum. The veins were engorged, but in no case was there evidence of mesenteric arterial occlusion. Digitalis has been shown to lower splanchnic blood flow and to increase splanchnic vascular resistance in patients with heart failure,[5] and such an effect may be critical when the mesenteric circulation is already compromised. It is possible that potassium depletion may also be a factor, since diuretics have commonly been given, and vomiting or diarrhoea will lead to further loss of potassium.

Such serious toxic effects deserve respect, and prevention is better than cure. The one indication for maintenance therapy with digitalis is atrial fibrillation, and the dose should seldom exceed the equivalent of 0.25 mg. digoxin twice daily, with a day's treatment omitted once a week. Patients with chronic heart failure may need less than this, and a careful watch should be kept for signs of toxicity or for a sudden change in tolerance to the drug. Any untoward symptom in a patient taking digitalis should raise the possibility of toxicity, and if in doubt the drug should be stopped. Early administration of potassium, chelating agents, or β-adrenergic blocking drugs may reverse the more serious toxic effects.

Therapeutic Misadventure

The numbers of deaths from therapeutic misadventure in England and Wales vary considerably from year to year. In 1959, for instance, they numbered 136. They then gradually rose to 220 in 1962, falling to 181 in 1963 and to 103 in 1964, the latest year for which figures have been published.[1] The present trend is therefore satisfactory, but the possibility that it is part of a largely chance fluctuation cannot yet be ruled out. Nor is the interpretation of the figures always entirely clear, because it is generally seriously ill patients who receive the most potent remedies, and in such circumstances the attribution of death to the effects of the treatment instead of to the disease can be problematical.

The latest report from the Registrar General[1] records 19 deaths from corticosteroids compared with 25 in 1963. This continues a downward trend from the total of 40 deaths in 1962. Similar substantial decreases in the numbers of deaths over the three years 1962–4 are recorded for those due to anticoagulants (21, 16, 9) and anti-cancer drugs (18, 16, 4). The number of deaths resulting from penicillin also dropped sharply, from 7 (plus 1 in conjunction with streptomycin) in 1963 to only 1 in 1964, and a considerable reduction is to be noted in deaths attributed to the results of radiotherapy, which fell from 46 to 32. In contrast two drugs previously known to cause death from therapeutic misadventure did not show much change—phenylbutazone, with 8 deaths in 1963 and 7 in 1964, and chloramphenicol with 6 and 4 respectively. Of the 74 deaths from surgical procedures it is notable that the operations of oesophagoscopy and dilatation of the oesophagus, together causing 12 deaths, stand out as much the largest group, as noted before in these columns.[2] The fatality in these cases followed on perforation of the oesophagus.

Papers and Originals

Post-concussional Sequelae*

ALEX. R. TAYLOR,† M.A., F.R.C.S.

Brit. med. J., 1967, 3, 67–71

After a year in which several papers have appeared describing a quantitative relationship between the late symptoms of head injury and measurable deviations from physiological and psychological norms (Houdart *et al.*, 1966 ; Lishman, 1966 ; Taylor and Bell, 1966), it would seem to be an appropriate time to re-examine a one-hundred-year-old question about the aetiology of post-concussional sequelae.

The same argument has ranged back and forth almost unchanged over this hundred years. In 1866 Erichsen presented 63 cases of severe injury sustained mostly on American railroads. He was concerned with the severity of the symptoms in the absence of much evidence of external injury. He thought the symptoms were due to molecular derangement of the spinal cord. In 1879 Regler, who had noted a great increase in the severity of symptoms after the introduction of compensation awards in 1871, expressed the view that they were actuated by fright, long inactivity, and a desire for financial gain. He thought there was no evidence for molecular derangement. This was the so-called "railway spine" controversy.

In 1962 Symonds reviewed the aetiology of concussion, and stressed, inter alia, the finding of cellular and diffuse white-matter damage. In 1966 Miller, analysing his experience of many head-injured litigants, wrote: "I cannot believe that the clinical features of this disorder justify its speculative attribution to cellular damage." This was a judgement about the writer's beliefs and not about concussion, but there is a good historical precedent for this too. In 1863, rejecting the then current vascular theories, Hilton wrote: "I cannot conceive it possible that a long continuance of the symptoms of concussion can depend upon any temporary error of this kind." Or again, Strümpell (1888) wrote: "I cannot free myself from a feeling of uncertainty in these cases of head injury."

It is worth while noting that in the early days of the argument the symptoms of "spinal concussion" preceded the inauguration of compensation payments, and that they were the same before as after, though their severity apparently increased. Indeed, the difference of opinion about aetiology has been bedevilled for 100 years by the inability of physicians to disentangle the symptoms occurring after concussion from the symptoms that follow the initiation of a claim for compensation. I have yet to read an article on the subject of post-concussional sequelae in the British literature which does not contain the words "litigation" or "psychogenic" in the first dozen lines. Even a critical leading article about post-traumatic headache, written in April 1966, which concluded that treatment was not easy but was well worth while, contained the statement that in at least two-thirds of the patients there is a psychogenic element. This is certainly an advance on a similar leader of 1961, which said: "Above all, the general physician . . . should find it advisable to refer a patient to the psychiatrist as soon as possible . . . " and concluded: "In the ultimate analysis it [accident neurosis] is a social disease and a function of industrial morale."

Symonds (1962) pointed out that it was valueless to inquire whether the symptoms were organic or functional, because they must always be both. While agreeing with this, I feel that a periodic critical analysis of degrees and probabilities is necessary with each advance in physiological or biochemical knowledge about head injury. The treatment of a disorder predominantly organic must be different from one predominantly psychiatric.

Prima facie, it seems strange that 66% of the head-injured, necessarily a random sample of the population, should be afflicted with neuroticism or excessive cupidity while most of the victims of limb, abdominal, or thoracic injury escape these stigmata. The evidence for neuroticism should be carefully examined.

Evidence for Neuroticism

There are no Abnormal Signs on Physical Examination

This is a notoriously difficult obstacle to precise diagnosis. That a patient should complain of organically determined symptoms of headache, dizziness, lack of energy, poor memory, and difficulty in concentrating and have no physical signs is to some doctors incredible. But the central nervous system is unique in its clinical silence.

A meningioma may attain the size of a cricket ball without causing more than an occasional epileptic fit or transient headache and give rise to no physical signs. A frontal or temporal lobe may be excised without definable abnormality, and thousands of patients have had all the white fibres of both prefrontal regions divided in the operation of leucotomy without detectable physical changes. Patients whose character, mood, and behaviour change after meningitis may have "negative" physical examinations. As Strauss and Savitsky (1934) concluded after a lengthy review of this question: "Failure to understand a clinical phenomenon is no proof of its psychogenicity."

There is an Inverse Relation Between Severity of Injury and Persistence of Post-concussional Sequelae

According to Miller (1961) the more trifling the injury the longer and more vehemently the litigant complains. Of his patients with a post-traumatic amnesia of less than 15 minutes 37% had gross unequivocal psychoneurotic complaints. Only 6% of patients with amnesia of over 72 hours had such complaints. Brock (1960), Russell and Smith (1961), and Symonds (1962) came to opposite conclusions about the significance of post-traumatic amnesia. They believed that though imperfect it was the most reliable and sensitive index of the severity of brain injury.

---

* Read at the Annual Clinical Meeting of the British Medical Association, Londonderry, 1967.

† Department of Neurological Surgery, Royal Victoria Hospital, Belfast 12.

The other comparison made by Miller to show that symptom severity varied inversely with physical damage was between those who had skull fractures and those who had not. Of nine cases with compound fractures none was complicated by neurosis, and "neurotic" symptoms were three times as common in those without as in those with fractures.

These data prove exactly the opposite of what was intended. Percivall Pott (1808) realized that a fracture might protect the patient against the general effects of brain deceleration. He listed vomiting, giddiness, loss of speech and sense, loss of voluntary motion, etc., as general symptoms, and then wrote: "On the other hand the bones of the skull are sometimes cracked, broken, nay even depressed, and the patient suffers none of these symptoms."

Denny-Brown and Russell (1941) found that an animal is rendered unconscious by a much lesser blow if the head is freely movable. The head not free to move is more easily fractured and suffers less of the effects of "cerebral commotion." A great deal of energy is absorbed in fracturing the skull, which is then diverted from the production of shearing stresses in the brain. For this reason biomechanics experts are exploring the possibilities of "tuning" a crash helmet so that it fractures under a certain stress and so protects the contained brain. One expects the patient with a fractured skull to suffer less from concussional effects than his unfractured counterpart who absorbed the same amount of energy on impact.

Unskilled Workers and Less-intelligent Patients Suffer More Prolonged Disability

This is a matter of interest and motivation, and is not confined to the field of trauma. During the last war Commando and Special Service personnel who were off duty for more than 21 days had to transfer to another unit. One could be certain that such selected men after operations for hernia, cartilage derangement, or disc protrusion would be out of bed as soon as permitted and back to their units probably suffering in silence within the statutory three weeks. Some prisoners of war or the more lowly performers of menial tasks in the Services could with difficulty be prised out of hospital in twice the time and be discharged, complaining bitterly, on sick leave.

Symonds and Russell (1943) found that head-injured R.A.F. air crews returned to duty twice as rapidly as ground personnel.

Similarly in civilian practice, the man with the more interesting job and the bigger personal stake in his recovery complains less and returns to his desk sooner.

Personal hazard is also a factor. A civil servant may be able to do his job efficiently in spite of some headache and a sense of abnormal movement, but a scaffold erector or steeplejack will not. Professional men will return to work sooner than manual workers, but it is incorrect to assume that they do not therefore have symptoms. Though 80% of Russell's (1933–4) patients (not entitled to compensation) returned to full work within six months of injury, 40% still had symptoms at the end of 18 months.

It is sometimes said that doctors do not suffer from post-concussional sequelae, but published accounts do not support this belief. Durand Wever (1929) described typical symptoms from an injury for which she was not entitled to claim compensation. Mayer (1929) found that his symptoms continued after his claim was settled, and advised other doctors to believe that their patients' complaints were both real and disabling. Strauss and Savitsky (1934) described a case in which a doctor had symptoms for five months after head injury without loss of consciousness. He continued to work but suffered from headaches, a sense of abnormal movement, lack of concentration, and poor effort tolerance. Compensation was not claimed.

Injuries Sustained during Sporting Activities do Not Have Sequelae

This generalization is partly true. It does not apply to severer ski-ing or rock-climbing accidents nor to "missile" injuries suffered on the hockey field. Hunting and rugby football are usually mentioned as "no-sequelae" sports, though American football, because of the dangerous "protective" devices worn, has abundant records of college boys who never played again after a head injury.

In physical terms this is a matter of speed at impact. The rugby player seldom achieves 20 ft. (6 m.) per second, the huntsman seldom comes off his horse at more than 30 ft. (9 m.) per second. The 30 mile (48 km.) an hour motorist is travelling at 44 ft. (13.4 m.) per second and twice that at 60 miles (96 km.) per hour. Graduation of severity according to speed of impact is well recognized in the Mid-western cities of America, where in hot weather small children stray to the stairs of tenement houses and fall through one or more flights. A fall of one flight, or 15 ft. (4.6 m.) (21 ft. (6.4 m.) per second), seldom results in injury requiring long detention in hospital, two flights (34 ft. (10.4 m.) per second) means a severe head injury, and three or more (44 ft. (13.4 m.) per second) may be fatal.

The question of motivation is again important; the sportsman does not want to give up a pleasurable form of activity, and, if necessary, will suffer the inconvenience of a headache.

Summary of Evidence for Neuroticism

The evidence for the predominance of neurotic symptoms after head injury is not very convincing, particularly if one disregards the litigants who obviously have a powerful motive, conscious and unconscious, for continuing to suffer.

If neurosis is such an important factor one would expect the literature to contain many controlled randomized studies of head-injured patients treated or not treated by psychiatric methods. No such studies exist. Instead are the statements that psychiatric treatment is of no value until claims for compensation are settled—patients not claiming compensation are never mentioned in this connexion. Surprisingly there is an absence of correlation between post-traumatic sequelae and history of previous psychiatric illness, which is mentioned in most reviews.

Though it is often said in our courts of law that recovery will begin at the conclusion of the case and be complete in two years, this is not borne out by 10-year surveys of the German head-injured of the first world war (Goldstein, 1942), or of the American Korean war head-injured (Caveness, 1966).

Of Goldstein's patients 20% became normal workers, 32% worked at one-half to one-third capacity, 30% had a below normal working capacity, and 18% did no work. These were largely missile injuries and not comparable to a civilian group, but the Korean series is equally divided between penetrating and blunt injuries. Of these patients 84% had returned to work after 10 years, but 40% still had symptoms and 27% had not made a satisfactory social and economic adjustment.

Known Organic Factors

That the initial signs of concussion and the symptoms immediately following recovery of consciousness are organic there is no doubt. Loss of consciousness, mass contraction of the limbs, cessation of respiration, rise in blood pressure, loss of corneal reflexes, and dilated pupils are followed by headache, perhaps vomiting, dizziness, confusion, and amnesia. These are all symptoms and signs which could arise from damage to the cranial nerve nuclei between the medulla (X) and the upper brain stem (III), the arousal centre in the reticular formation, the pyramidal tracts, and the vasomotor centre. If damage is sought in the brain of the concussed animal this is the area in which it is mainly found. The nerve cell count in the lateral vestibular nucleus is invariably reduced even after a mild concussional blow. That this is not transitory was shown by Groat and Simmons (1950), who made cell counts in the brain-stem nuclei of guinea-pigs 13 months after a single concussive blow to the movable head.

The mechanism of the medullary injury is uncertain. It may be, as Friede (1961) suggested, a blow to the cervico-medullary junction dealt by the odontoid process as the anterior surface is hyperflexed over it. The brain stem and cord are more probably stretched than struck, as the neck is hyperflexed through about 110 degrees and rapidly decelerated. Breig (1960) demonstrated that the cord is stretched and elongated on neck flexion. As it is fixed by the filum terminale, dentate ligaments, and cranial nerves, especially V, VII, and VIII, this pull will be sharply felt all through the brain stem and forward through the long tracts to where the forebrain is fixed by the optic nerves, olfactory bulbs (sometimes pulled out), and carotid arteries. As a result of this stretching white fibres from the brain stem to the centrum ovale are actually fractured or snapped. Biggart (1936) demonstrated these "fractures" and the resulting end bulbs on the axons by Bielschowsky staining in the brains of patients dying after head injury. But these lesions are present not only in fatal injuries. Nevin (1964) found them all through the white matter of rats subjected to even minor concussive blows. They took about three days to develop (Fig. 1) and were present as constantly as the chromatolysis in the brain stem nuclei described by Windle *et al.* (1944) (Fig. 2). In the same areas he found irregular thickening and fragmentation of the myelin sheaths (Fig. 3).

If concussion causes widespread lesions throughout the white matter it is not surprising that Becker *et al.* (1946) found a deterioration in the maze-running performance of guinea-pigs a month after concussion. Animals already trained lost their skills, while untrained animals were much more difficult to train and retained their new learning badly compared with control animals. It seems more reasonable, therefore, to suppose that injured human subjects concentrate and learn badly, find difficulty in retaining new information, are irritable, anxious, and lacking in insight because they have multiple lesions throughout the white matter, than to label them neurotic because they do not have any of the easily elicited physical signs.

Variations from the Physiological Norm

Though patients after uncomplicated concussion do not have abnormal physical signs, they have been found by special examination to show deviations from normality in the permeability of the blood/C.S.F. barrier, cerebral blood flow, and vestibular responses to threshold stimuli (electronystagmography). Zetterholm (1947) examined 149 head-injured patients six months to two years after head injury for permeability of this blood/C.S.F. barrier to bromine. Of 104 who had normal permeability quotients 63 had no sequelae and only four had severe symptoms. Only eight of 45 with abnormal permeability quotients had no sequelae, and 15 had severe symptoms.

After two years 73 patients were re-examined: 57 were normal, of whom 47 had no sequelae and none was severely

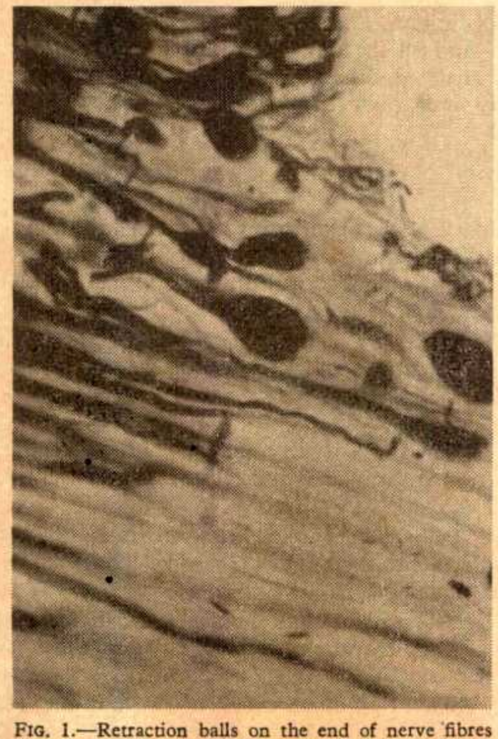

FIG. 1.—Retraction balls on the end of nerve fibres from a rat 10 days after concussional head injury. (Bielschowsky. ×350.)

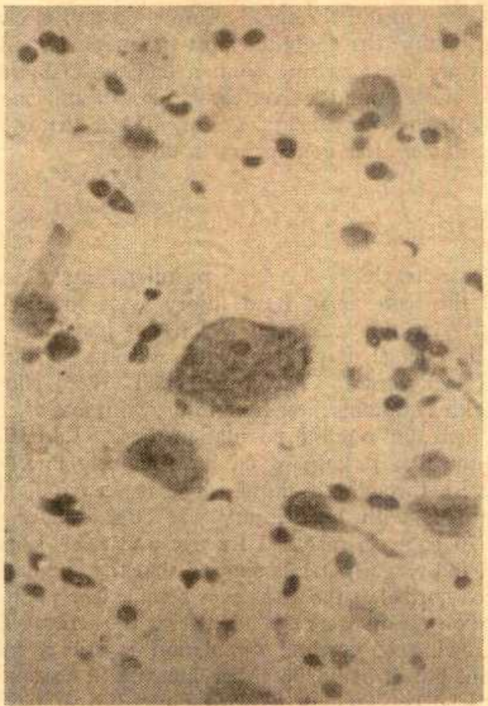

FIG. 2.—Nerve cells in the medulla oblongata showing chromatolysis three days after injury. (Gallocyanin. ×265.)

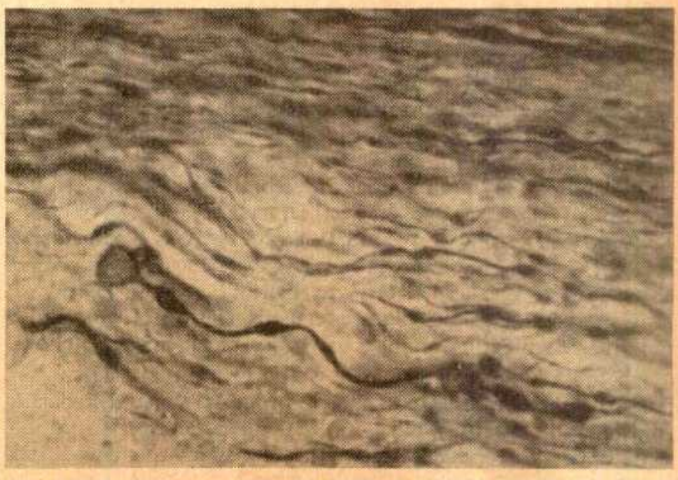

FIG. 3.—Myelin sheaths showing fusiform swelling and vacuole formation seven days after concussion. (Weigert Pal. ×320.)

disabled. Of the 16 with abnormal permeability 12 had sequelae, seven of a severe degree. These figures are statistically significant. The findings have been confirmed by Haxhe (1963), using radioactive bromine. They indicate that one of the effects of brain injury is altered blood/C.S.F. permeability and that its degree correlates with the severity of postoperative sequelae.

Vestibular Function

Though much has been written about labyrinthine damage in head injury Friedman *et al.* (1945) showed that tests of vestibular function did not place the lesion causing post-concussional dizziness in the labyrinth. Since then testing has been greatly refined and includes the electrical recording of nystagmus (electronystagmography). In this way Houdart *et al.* (1966) studied 50 patients with "a subjective syndrome following injuries to the head." In more than half they found a vertical nystagmus appearing in all positions of the head. There were additional minor abnormalities of rhythm and amplitude which they thought were "specific to the traumatic syndrome and apparently authenticating its organic basis." Wilmot (1966), using threshold stimulation and electronystagmography, found the abnormal post-traumatic responses quite different from those arising from a damaged labyrinth; and similar to those found in vertebrobasilar insufficiency. This accords with the experimental finding of chromatolysis in the vestibular nuclei after concussion in animals.

Vascular Factors

Vasomotor instability has been postulated as an aetiological factor in the sequelae of head injury since the earliest days of inquiry. By this was originally meant instability of blood pressure on change of posture with resulting dizziness, faintness, and tachycardia. Taylor and Bell (1966) showed that patients with symptoms after head injury with loss of consciousness had increased cerebral circulation times. Recordings were made of the first passage of an intravenously injected radioactive stream through the head. The mean circulation times of 70 patients with head injury was 20% greater than the mean of 70 controls matched for age and sex. Longitudinal studies of individual patients showed that the circulation times approached normal as the symptoms became less. Patients with compensation claims were excluded from the series. The cause of this slowing of cerebral circulation is still a matter for speculation, but it could be either increase in vasomotor tone at the arterial or capillary level or increased capillary permeability.

Discussion

There is now a great deal of pathological, physiological, and biochemical data to show that patients who absorbed a blow on the head sufficient to cause alteration in consciousness have lesions of varying severity in the medullary pontine nuclei and the white matter, with consequent disorders of vestibular function, capillary permeability, and cerebral blood flow. Minor intellectual disorders are found if sought for by objective psychological testing (Zangwill, 1966). There is also evidence of acute disorders in glucose and pyruvate metabolism (Kurze *et al.*, 1966), water and electrolyte distribution (Van Harreveld, 1966), adenosine triphosphate metabolism (Ishii, 1966), and a rapidly accumulating number of other biochemical reactions.

It is no longer good enough to stand firm on clinical convictions that head-injured patients, if properly managed, socially adjusted, and carefully rehabilitated, will not have "neurotic" symptoms. The evidence from the few series so managed all points in the other direction. We cannot therefore say that the patients have their symptoms because they have been neglected, spoiled, or legally implicated. It is increasingly clear that closed head injury may present any degree of chronic complication from the slightest abnormality to dementia and quadrispasticity (Strich, 1961). Patients who have minor difficulties in concentration and performance which irritate them and make them act unusually are not "neurotic," they are "cerebrally disorganized," and for good organic reasons. How else can we explain the child who comes in from play and asks to be allowed to lie down because he has a headache, the active young man who discovers to his surprise that he is sensitive to the effects of alcohol, or the older man whose family says "he has never been the same since his fall"?

These symptoms are important, firstly, because for all we know they may be preventable, and, secondly, because the number of sufferers increases steadily every year.

They may be preventable—the investigation of the concussed patient stops after neurological examination at skull *x*-ray examination, and treatment is rest in bed until he is well enough to get up. The number of sufferers increases—head injury is now by far the commonest neurological disorder. In Great Britain traffic accidents, industrial injuries, and miscellaneous falls cause over half a million head injuries each year. Of these, 80% are classified as non-dangerous, but about 40% have "concussion" and 15% have continuing symptoms. In round figures there are about 75,000 new patients with post-traumatic symptoms added to the existing number each year. The profession will soon be forced by the magnitude of the problem to take some note of it.

It does not appear as if propaganda or prophylactic measures will reduce the number of traffic accidents. They continue to increase annually in every country along with the climbing traffic density. We shall have to treat the resulting patients, and as a necessary prerequisite we shall have to discover much more than we now know about the physiological and biochemical disorders of acute and chronic post-concussional states. The present surgical endeavour in the treatment of head trauma is almost wholly absorbed in the diagnosis of intracranial bleeding and its treatment. We do everything for the severely damaged 10% and neglect the non-serious 90%. The only head injury sequelae we remotely begin to understand is epilepsy, because it can be observed, assessed, and treated. The less tangible symptoms—headaches, vertigo, irritability, poor concentration, faulty memory, sensitivity to alcohol, loss of libido—and all the other pieces of this so-called syndrome should be analysed, dissected, and investigated until it is known what they are, what they express, and how they can be corrected.

Summary

The history of the relationships between litigation and head trauma and its neurotic sequelae is presented. It is noted that there is a higher rate of so-called neuroticism after head trauma than after trauma to other parts.

The evidence that concussional sequelae are in fact neurotic is examined in detail. It is concluded that, except in litigants, the evidence is poor.

The known organic factors in patients who have symptoms after concussional head injury are reviewed. The influence of lesions seen in the midbrain and white matter of experimentally concussed animals is considered.

A relationship is suggested between these diffuse minor lesions and the emotional and intellectual abnormalities found after head trauma.

Physiological and biochemical changes are described affecting the blood/C.S.F. barrier, cerebral circulation times, and tests of vestibular function.

It is concluded that management of the head-injured patient is based on too many unwarrantable assumptions about the incidence of neuroticism and the absence of important physical

and biochemical abnormalities. It is suggested that research into the large and important group of "non-serious" head injuries has been neglected, to the detriment of their management.

Figs. 1, 2, and 3 are reproduced by kind permission of Dr. N. C. Nevin.

Brit. med. J., 1967, **3**, 71–74

Mid and late systolic clicks and late systolic murmurs have in the past been regarded as "innocent," and were thought to be due to pericardial adhesions (Wells, 1957; McKusick, 1958; Ongley *et al.*, 1960; Segal and Likoff, 1964). Recently there has been evidence to show that these auscultatory findings are due to an abnormality of the mitral valve and sometimes are associated with a history of anterior chest pain and an abnormal electrocardiogram (Barlow *et al.*, 1963; Barlow, 1965; Tavel *et al.*, 1965; Barlow and Bosman, 1966; Criley *et al.*, 1966; Leon *et al.*, 1966; Linhart and Taylor, 1966). The purpose of this paper is to present our findings in 13 patients with mid or late systolic clicks and late systolic murmurs, with particular reference to the familial nature of this entity and the findings on left ventricular cineangiography and selective coronary arteriography.

Methods and Materials

Of the 13 patients studied six were referred with anterior chest pain, four because a murmur had been detected on routine examination, and three were siblings of patients already known to us. All were assessed clinically, and an electrocardiogram and a phonocardiogram were made. In six cases haemodynamic studies and left ventricular cineangiography were carried out. Selective coronary arteriography was performed in two patients who presented with severe anterior chest pain.

Findings

The clinical features are set out in Table I. There was a definite female preponderance in the series, 11 patients being female and two male. Their ages ranged from 28 to 67, with a mean of 46 years.

Chest pain was a significant symptom in six patients. The pain occurred anteriorly in the chest, was stabbing in quality, and was not related to exertion. In two cases it was severe enough to require analgesics by injection, but most patients had been regarded as suffering from "cardiac neurosis." In no case was there a past history of rheumatic fever or a history of an illness which in retrospect could have been pericarditis. One patient had been involved in a motor-car accident shortly before the murmur was detected, but she could recall no chest injury. Two patients had thyrotoxicosis; one had symptoms of this at the time her murmur was detected and the other developed it subsequently. One patient had been thought to have had a myocardial infarct some years previously, but there was no evidence of this on her electrocardiogram.

The family history was of significance in only one patient whose father and four brothers were said to have coronary artery disease. However, because a familial incidence of this entity had been suggested, we examined the siblings of our

V.E.S. = Ventricular extrasystoles. L.V.H. = Left ventricular hypertrophy.

patients as the opportunity arose. Three sisters in one family (Cases 1–3) had similar auscultatory findings (Fig. 1): haemodynamic studies were carried out in one of them. In the second family two sisters (Cases 4 and 5) had similar auscultatory findings (Fig. 2), though their brother and the children of one of them were normal. The half-sister and three children of another patient (Case 6) were examined and found to be normal.

The abnormal findings in all cases were limited to auscultation. In no case was there any clinical evidence of ventricular hypertrophy or cardiac failure, and all had normal blood pressure. The first and second sounds were normal, but in all cases clicks were present. In seven cases the click was late-systolic, in two cases mid-systolic, and in four cases multiple. In nine cases a late systolic murmur (Fig. 3) was heard, loudest at the apex, but in two cases isolated clicks were the only abnormal findings. In one case the murmur was very loud and " musical," varying with posture (Fig. 4). The remaining two patients had systolic murmurs.

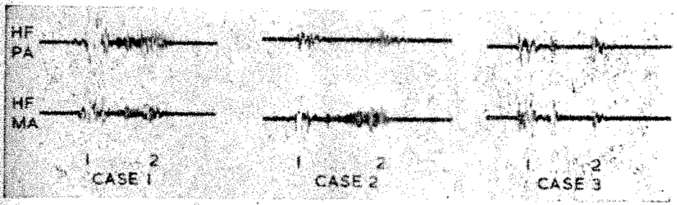

Fig. 1.—Phonocardiograms of three sisters showing first and second heart sounds (1 and 2), the mid-systolic click, and the late systolic murmur. (PA = pulmonary area ; MA = mitral area ; HF = high frequency.)

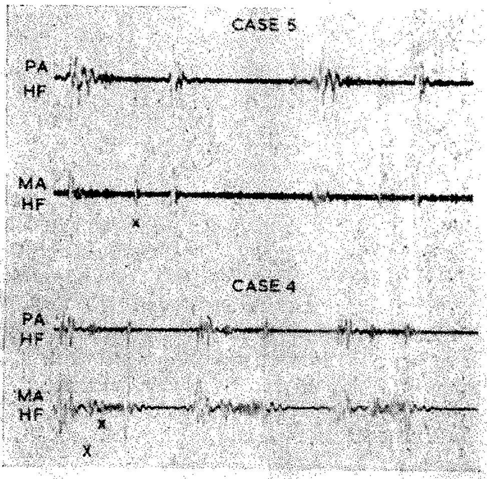

Fig. 2.—Phonocardiograms of two sisters showing the systolic click and late systolic murmur.

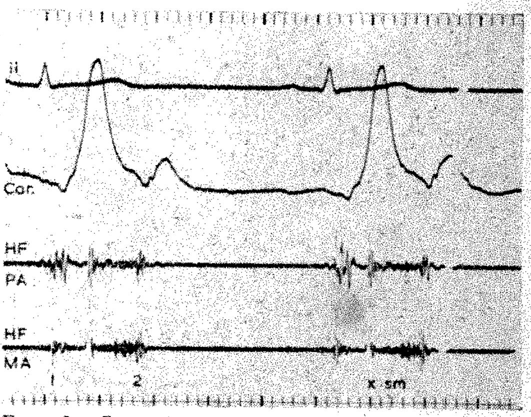

Fig. 3.—Case 9. Phonocardiogram showing the characteristic mid-systolic click (X) and late systolic murmur (SM). (ii = electrocardiogram lead II, Car. = carotid tracing, PA = pulmonary area, MA = mitral area, HF = high frequency.)

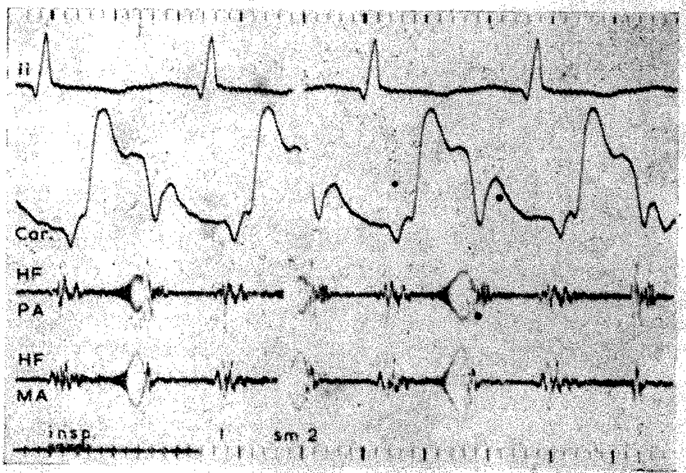

Fig. 4.—Case 4. Phonocardiogram showing loud " musical " late systolic murmur.

The electrocardiograms did not show any constant abnormality. In four patients they were normal. In two of these severe chest pain was the presenting symptom, but no abnormalities appeared during pain or after exercise on a treadmill. In another four left ventricular hypertrophy could be diagnosed (S in V1+R in V5>35 mm.)—in three in association with ST–T wave abnormalities. Four patients had ST or T wave abnormalities alone (see Table I) (in leads II, III, AVF, and the lateral chest leads) and one patient had a partial right bundle-branch block. Ventricular extrasystoles were present in three cases (Figs. 5 and 6). The chest *x*-ray picture in all cases was regarded as being within normal limits, there being no cardiomegaly, left atrial enlargement, or intracardiac calcification. Haemodynamic studies were carried out in six patients (Table II), and in all cases were normal. In particular there was no elevation of the left atrial pressure (pulmonary artery wedge) or of the left ventricular end-diastolic pressure, indicating that the mitral regurgitation was mild.

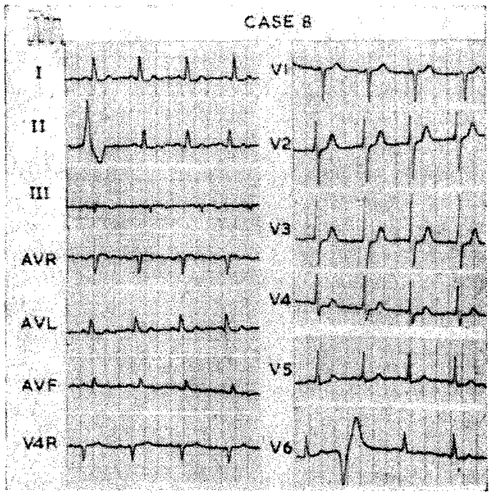

FIG. 5.—Case 8. Electrocardiogram showing ventricular extrasystoles and ST–T wave changes.

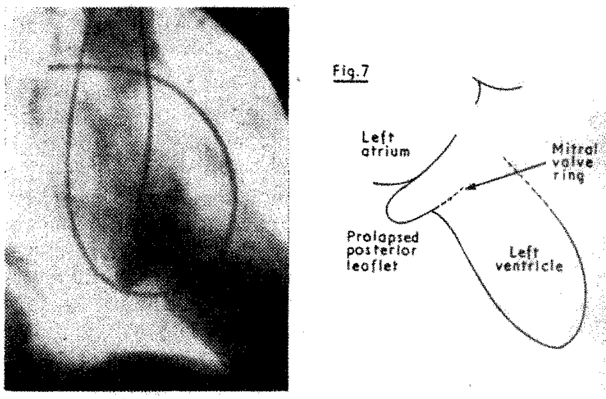
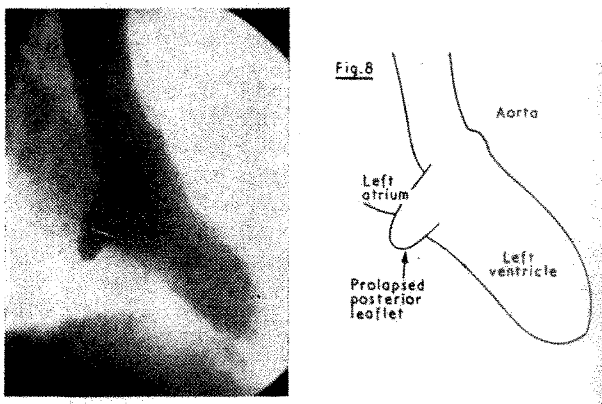
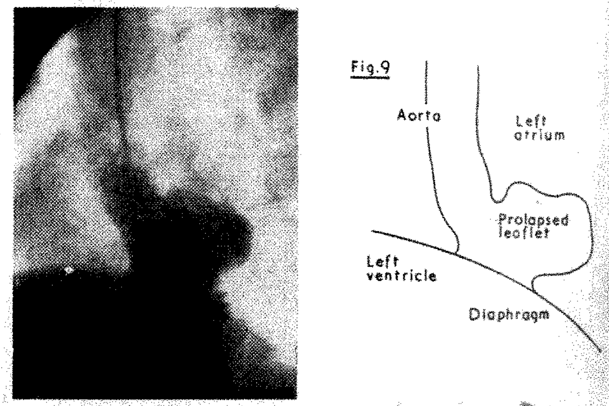
Left ventricular cineangiography was carried out in six patients. The mitral valve was studied in all six in the right anterior oblique position and in four of these in the left anterior oblique position with the head of the table raised 15 degrees. Prolapse of the posterior leaflet of the mitral valve into the left atrium during ventricular systole was demonstrated in all cases (Figs. 7, 8, and 9). Late mitral regurgitation was present in the five patients with a late systolic murmur, but was absent in the patient with an isolated click.

In addition, selective coronary arteriography was performed in the two patients with severe chest pain, and in both cases the coronary arteries showed no abnormality. The coronary arteries showed no evidence of atheroma and all major branches could be seen clearly, including the branches along the diaphrag-







FIGS. 7 and 8.—Left ventricular angiograms (and line drawings) in right anterior oblique position showing prolapse of the posterior le of the mitral valve into the left atrium and mitral regurgitat FIG. 9.—Left ventricular angiogram (and line drawing) in the left ante oblique position, with the head of the table elevated 15 degrees, show prolapse of the posterior leaflet of the mitral valve into the left atri matic aspect of the heart which supply the papillary muscles (James, 1965). There was no evidence of phasic narrowing of the circumflex artery during ventricular systole.

Discussion

We consider that the finding of a mid or late systolic click and a late systolic murmur in the mitral area is suggestive, if not diagnostic, of prolapse of the posterior leaflet of the mitral valve. Few patients have been investigated, but all reports to date have confirmed the presence of this abnormality in those patients with the characteristic auscultatory findings. Barlow and Bosman (1966) investigated only those patients with an abnormal electrocardiogram, but we have shown, as have other authors, that this is not necessary for diagnosis.

The cause of the chest pain and the abnormal electrocardiogram, where present, remains obscure. Barlow and Bosman (1966) have suggested that the prolapsing posterior leaflet causes compression of the circumflex branch of the left coronary artery, and that ischaemia of the posterior myocardium results. Selective coronary arteriography was performed in two of our patients because of the presence of severe chest pain, but in neither case was there any evidence to support this hypothesis.

The familial incidence of this entity has been noted by other authors, and we have confirmed this in two families. Extensive family studies were not carried out, and we therefore do not know whether the lesion is usually familial.

There was no other obvious aetiological factor. Mitral incompetence has been described after chest injury (McLaughlin *et al.*, 1964), but the only patient with a past history of chest injury had two siblings similarly affected. Rheumatic fever or pericarditis could not be diagnosed, even retrospectively, in any case. Phillips *et al.* (1963) have described a late systolic murmur after papillary muscle infarction, and it was thought that the chest pain might have been indicative of papillary muscle ischaemia, leading to a functional abnormality of the chordae tendineae. However, we have demonstrated that the valve abnormality can exist in the absence of either chest pain or coronary artery disease. Barlow and Bosman (1966) have also described this lesion in association with Marfan's syndrome, but none of our patients had stigmata of this condition.

Leon *et al.* (1966) have shown that both the click and the murmur arise from the mitral valve, and Criley *et al.* (1966) have recorded that the click corresponds with the maximal ballooning of the posterior leaflet. The click therefore presumably arises either from stretching of the posterior leaflet itself or from its attached chordae tendineae. The late systolic murmur is due to mitral regurgitation occurring late in systole, and was absent in the patient in whom prolapse of the posterior leaflet without regurgitation was demonstrated.

In all the patients studied to date no material has been available for anatomical investigation. However, Barlow (personal communication, 1966) has described marked enlargement of the posterior leaflet of the mitral valve at necropsy in a patient who had a late systolic murmur and a "non-ejection" click. In addition there have been reports (Osmundson *et al.*, 1961 ; Hudson, 1965) of the finding of a "hooded" or "parachute" deformity of the posterior leaflet of the mitral valve at post-mortem examination, though in these cases there was no record of the auscultatory findings. Normally the posterior leaflet of the mitral valve occupies only one-third of the total valve area (Chiechi *et al.*, 1956), and therefore it would seem that in these cases there is an actual increase in the size of the posterior leaflet of the mitral valve. There is also support for the theory that the prolapse of the posterior leaflet of the mitral valve is due to an abnormality of the attached chordae tendinae. Four normal hearts were dissected in order to study the anatomy of the chordae tendineae attached to the posterior leaflet of the mitral valve. When the chordae tendineae of the "third order" (Chiechi *et al.*, 1956) were severed it was seen that prolapse of the posterior leaflet into the left atrium could occur, whereas when a major chorda tendinea was severed the valve became completely incompetent. We therefore believe that the anatomical abnormality in these patients will prove to be enlargement of the posterior leaflet of the mitral valve together with an abnormality of the chordae tendineae or papillary muscles.

It has been suggested by Linhart and Taylor (1966) that prophylaxis for bacterial endocarditis should be administered to these patients. However, the majority of our patients had had most or all of their teeth extracted without developing bacterial endocarditis, and therefore prophylaxis may be unnecessary.

It has also been suggested that the mitral regurgitation in this condition may ultimately reach a sufficient degree to warrant surgery (Linhart and Taylor, 1966). This is of course possible, but in our patients subjected to haemodynamic studies there was no evidence of cardiac decompensation, even in those past middle age. In one of our patients the prolapse was associated with a systolic click without a late systolic murmur or mitral regurgitation. This patient will be followed closely to see if the late systolic murmur and mitral regurgitation eventually develop.

Summary

Thirteen patients with mid or late systolic clicks and late systolic murmurs were studied. Haemodynamic studies and left ventricular angiography were performed in six of these, and confirmed the presence of prolapse of the posterior leaflet of the mitral valve and mitral regurgitation. Coronary artery disease as the cause of chest pain and an abnormal electrocardiogram was not confirmed on selective coronary arteriography. The familial nature of this entity was confirmed.

We wish to thank the physicians of the Royal Melbourne Hospital who referred patients for study. The line drawings were done by Miss J. Miles.

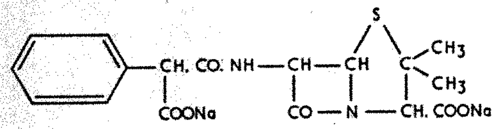
Carbenicillin[*]: A New Semisynthetic Penicillin Active against *Pseudomonas pyocyanea*

E. T. KNUDSEN,[†] M.B., B.S., F.C.PATH.; G. N. ROLINSON,[†] D.SC.; R. SUTHERLAND,[†] B.SC.

Brit. med. J., 1967, 3, 75–78

Carbenicillin (disodium α-carboxybenzylpenicillin; BRL 2064) is a new semisynthetic penicillin with a wide spectrum of activity against Gram-positive and Gram-negative bacteria. In particular, carbenicillin shows a certain level of activity against *Pseudomonas pyocyanea* (*Pseudomonas aeruginosa*), and the compound is also active against many strains of *Proteus vulgaris, Proteus rettgeri,* and *Proteus morganii,* which are typically resistant to ampicillin.

The structure of carbenicillin is as follows:



The compound, which should be stored in the refrigerator, is readily soluble in water, giving a clear neutral solution, which shows no significant loss of activity after 24 hours at room temperature and is stable in the refrigerator for at least seven days. In acid solution carbenicillin is relatively unstable, the half-life at *p*H 2 being approximately two hours at room temperature and approximately 30 minutes at 37° C.

Antibacterial Activity of Carbenicillin

The antibacterial spectrum of carbenicillin is shown in Table I. Minimum inhibitory concentrations were determined by serial dilution of the drug in agar, and one drop of an overnight broth culture of each organism was used as inoculum.

TABLE I.—*Antibacterial Spectrum of Carbenicillin*

	Minimum Inhibitory Concentration (µg./ml.)*
Escherichia coli	5·0
Klebsiella aerogenes	250
Salmonella typhi	12·5
Shigella flexneri	5·0
,, *sonnei*	5·0
Pseudomonas pyocyanea	50
Proteus mirabilis	2·5
,, *morganii*	5·0
,, *rettgeri*	2·5
,, *vulgaris*	5·0
Haemophilus influenzae	0·5
Staphylococcus aureus Oxford	0·5
,, *aureus*†	50
β-Haemolytic streptococcus	0·25
Streptococcus faecalis	25
,, *pneumoniae*	0·5
Bacillus subtilis	1·25
Sarcina lutea	0·5
Clostridium tetani	0·25
,, *welchii*	0·25

* Serial dilution in agar; inoculum, one drop of an overnight culture.
† Penicillinase-producing strain.

Carbenicillin is active against *Escherichia coli, Salmonella* species, *Shigella* species, *Proteus mirabilis*, and *Haemophilus influenzae,* and in this respect the spectrum of activity is similar to that of ampicillin, although carbenicillin is in general rather less active than ampicillin. Most strains of *Klebsiella aerogenes* are resistant to carbenicillin and the level of activity against enterococci (*Streptococcus faecalis*) is relatively low. Carbenicillin is active against pyogenic streptococci, pneumococci, and penicillin-sensitive strains of staphylococci, although the compound is considerably less active in this respect than penicillin G or ampicillin. Carbenicillin is not stable to staphylococcal penicillinase and is not active against penicillin-resistant strains of staphylococci. The activity of carbenicillin against several strains of *Pr. vulgaris*, *Pr. rettgeri*, and *Pr. morganii* is shown in Table II. These species of proteus are characteristically resistant to ampicillin, and in the experiment shown in Table II all the strains required an ampicillin concentration of at least 50 µg./ml. to prevent growth. In contrast, many of these strains were relatively sensitive to carbenicillin and in some cases were inhibited by concentrations as low as 1.25 µg./ml. Strains of *Pr. mirabilis,* however, which are resistant to ampicillin are also resistant to carbenicillin. The reason for the activity which carbenicillin shows against certain ampicillin-resistant proteus appears to be due to greater stability of the compound towards the penicillinases produced by these organisms. On the other hand, penicillinase-producing strains of *Pr. mirabilis*, like those of *Kl. aerogenes*, inactivate both carbenicillin and ampicillin.

TABLE II.—*Activity of Carbenicillin Against Ampicillin-resistant Strains of Proteus*

		Minimum Inhibitory Concentration (µg./ml.)*	
		Carbenicillin	Ampicillin
Proteus morganii	A	1·25	50

vulgaris	I	2·5	250
	A	5·0	125
	E	5·0	250
	G	50	> 500
	H	250	> 500
,, *mirabilis*	8	> 500	> 500
	889	> 500	> 500

* Determined by serial dilution in agar. The inoculum was one drop of an overnight broth culture, and M.I.C. values were read after 18 hours at 37° C.

The most significant feature of the antibacterial spectrum of carbenicillin is the activity against *Ps. pyocyanea*. In terms of the minimum inhibitory concentration the activity against this pathogen is relatively low, since for most strains a concentration in the order of 50 µg./ml. is required to prevent growth. However, from the clinical point of view activity is essentially meaningful in relation to the concentration of drug which can be reached at the site of infection. Carbenicillin itself is remarkably free from toxic effects (Acred *et al.*, 1967) and can be administered in sufficient dosage to obtain concentrations in the serum which are inhibitory to typical strains of *Ps. pyocyanea*, and the drug is also excreted in high concentration in the urine.

One characteristic of the activity of carbenicillin against *Ps. pyocyanea* is that in serial dilution tests to determine the minimum inhibitory concentration the drug does not show a sharp end-point when the inoculum is very heavy. This is illustrated in Fig. 1. Serial dilutions of carbenicillin in nutrient agar were prepared in Petri dishes and an area of the agar surface of each plate was inoculated with an undiluted overnight broth culture of a strain of *Ps. pyocyanea* applied with a cotton-wool swab. In this way the inoculum on each plate was at least 10 million organisms. A similar series of plates was also inoculated in the same way, using the same culture of *Ps. pyocyanea* but diluted 1/100 to give an inoculum of approximately 100,000 organisms. The strain of *Ps. pyocyanea* used in this experiment was a recent clinical isolate and was typical with regard to its sensitivity to carbenicillin. With the use of the undiluted culture as inoculum growth was very markedly diminished at a concentration of 25 μg./ml. carbenicillin, but a number of colonies were present even at a concentration of 50 μg./ml. and growth could only be said to have been prevented on the plate containing 125 μg./ml. However, when the inoculum was diluted 1/100 inhibition of growth was very pronounced at a concentration of 12.5 μg./ml., and at a concentration of 25 μg./ml. only three or four colonies were seen.

---

[*] Pyopen is the registered trade mark of Beecham Research Laboratories for carbenicillin.
[†] Beecham Research Laboratories, Brentford, Middlesex.

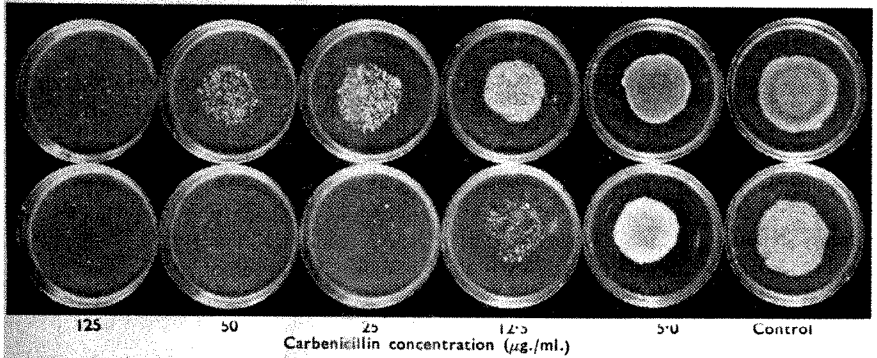

Fig. 1.—Activity of carbenicillin against a typical strain of *Ps. pyocyanea*. Serial dilutions of carbenicillin in nutrient agar were prepared in Petri dishes and an area of the agar surface of each plate was inoculated, using a cotton-wool swab. An undiluted overnight broth culture of *Ps. pyocyanea* was used to inoculate the upper row of plates and a 1/100 dilution of the same culture was used to inoculate the lower row.

Thus, in experiments of the type shown in Fig. 1, with the use of typical strains of *Ps. pyocyanea* and a very heavy inoculum level, some scanty growth may be seen with concentrations of carbenicillin as high as 125 μg./ml., and consequently if the criterion of the "minimum inhibitory concentration" is one of complete inhibition of all trace of growth the M.I.C. with a heavy inoculum may well be as high as 250 μg./ml. or more. However, the amount of growth at such concentrations is extremely meagre indeed, and with an inoculum only slightly smaller a sharp end-point is seen with complete inhibition of growth at a concentration of carbenicillin of 25–50 μg./ml.

Minimum inhibitory concentrations of carbenicillin for 111 clinical isolates of *Ps. pyocyanea* are shown in Table III. These inhibitory concentrations were determined by preparing serial dilutions of carbenicillin in agar as described above, and one drop of a 1/100 dilution of an overnight broth culture of each isolate was used as inoculum. It will be seen from Table III that the majority of the strains were inhibited by a concentration of 25–50 μg./ml. carbenicillin. In comparison, the inhibitory concentrations of ampicillin and benzylpenicillin against most strains of *Ps. pyocyanea* are of the order of 1,000–5,000 μg./ml. or greater.

Table III.—*Activity of Carbenicillin Against Pseudomonas pyocyanea*

No. of Strains	Minimum Inhibitory Concentration (μg./ml.)* and No. of Strains					
	250	125	50	25	12·5	5·0
111	5	8	61	31	6	

* Determined by serial dilution in agar. The inoculum was one drop of a 1/100 dilution of an overnight broth culture, and M.I.C. values were read after 18 hours at 37° C.

The effect of the inoculum size on the determination of the minimum inhibitory concentration is not due to destruction of the drug as in the case of penicillin G and penicillin-resistant staphylococci. Carbenicillin is itself stable to the penicillinase produced by typical strains of *Ps. pyocyanea*. Furthermore, the effect of inoculum size does not appear to be due to growth of resistant mutants present in a large inoculum. When tests are carried out using as inoculum the growth which occurs in the presence of high concentrations of carbenicillin the result obtained is the same as that seen with the original culture—that is, marked suppression of growth at concentrations of 25 μg./ml., but with scanty growth nevertheless persisting up to a concentration as high as 125 μg./ml.

As might be expected, this effect of inoculum size on the minimum inhibitory concentration of carbenicillin is also seen with tests carried out in liquid medium. With a heavy inoculum—for example, one drop of undiluted broth culture—growth appears normal with formation of pigment and pellicle up to a concentration of approximately 12.5 μg./ml. carbenicillin, but at 25 μg./ml. there is generally absence of pellicle and pigment and a markedly diminished amount of growth, although complete inhibition of growth may be obtained only with concentrations as high as 250 μg./ml. With a slightly smaller inoculum a sharp end-point is obtained, and with most strains of pseudomonas the minimum inhibitory concentration under these conditions is usually about 50 μg./ml.

Carbenicillin is bactericidal, and typical results with a strain of *Ps. pyocyanea* are shown in Fig. 2. Over the first seven hours a concentration of 50 μg./ml. usually results in a kill of at least 99% of the original inoculum, but thereafter some resumption of growth takes place which may even increase to a visible amount after 24 hours. When this growth is used as inoculum in a repeat test the same kill is again obtained over the first seven hours, followed by a certain amount of growth. The reason for this bactericidal effect followed by growth is not known, but it would not appear to be due to the selection of resistant mutants present in the original inoculum, nor is it due to inactivation of carbenicillin during the experiment.

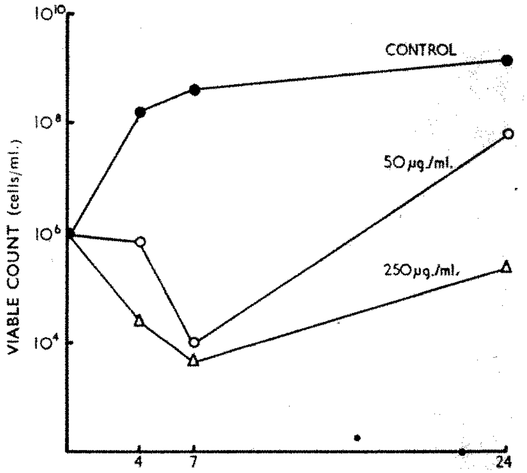

Fig. 2.—Bactericidal activity of carbenicillin against *Pseudomonas pyocyanea*.

Development of Resistance

Experiments involving repeated subculture of staphylococci and various Gram-negative bacilli, including *Ps. pyocyanea*, in the presence of carbenicillin, indicate that emergence of resistance takes place in a stepwise fashion which is characteristic of penicillins.

Effect of Serum on Activity

Carbenicillin is not highly bound to serum proteins. Sensitivity tests carried out in human serum show that the activity of carbenicillin is not significantly diminished in the presence of serum. Determinations of the extent of binding by ultrafiltration indicate that in human serum approximately 53% of the drug is unbound.

Disc Sensitivity Testing with Carbenicillin

With 6-mm. paper discs containing 100 μg. carbenicillin all strains of *Ps. pyocyanea* tested in this laboratory have given zones of inhibition of 12–20 mm. with a heavy inoculum and zones of 18–30 mm. with a dilute inoculum. With a heavy inoculum a number of colonies are usually visible within the zone of inhibition, although when these colonies are picked off and retested they show the same sensitivity as the original culture and again give rise to a number of colonies within the clear zone of inhibition.

In the case of Gram-negative bacilli other than pseudomonas—for example, *E. coli* and *Proteus* species—a 25-μg. disc would be suitable for sensitivity testing. With use of a heavy inoculum inhibition zones of 20 mm. or more are usually obtained with strains that are inhibited by 5 μg./ml. carbenicillin.

Absorption and Excretion in Man

Assay of Carbenicillin in Serum and Urine

The concentration of carbenicillin in serum and in urine was determined by the cup-plate biological assay method. Details of the technique were as previously described (Knudsen and Rolinson, 1960) except that *Ps. pyocyanea* NCTC 10490 (Ellsworth strain, 1973) was used as test organism. *Sarcina lutea* and *Staphylococcus aureus* are unsuitable as assay organisms because carbenicillin contains a small amount of benzylpenicillin and this may appear in the serum and in the urine together with the carbenicillin. Since *S. lutea* and *Staph. aureus* are many times more sensitive to benzylpenicillin than to carbenicillin, the presence of traces of benzylpenicillin may invalidate the assay. *Ps. pyocyanea* NCTC 10490, on the other hand, is sensitive to carbenicillin but relatively resistant to benzylpenicillin. The culture is unusually sensitive to carbenicillin, showing a minimum inhibitory concentration of approximately 1.25 μg./ml., and using this strain it is possible to assay concentrations of carbenicillin as low as 2.5 μg./ml., while benzylpenicillin at concentrations of up to 500 μg./ml. fails to show any zone of inhibition. Standard solutions of carbenicillin from 1 to 100 μg./ml. were prepared in human serum, and, where necessary, serum specimens were suitably diluted in human serum to give a level within this range of concentration. For the assay of urine samples the standard solutions of carbenicillin were prepared in M/20 phosphate buffer *p*H 7, and urine samples were also diluted as required, using the same buffer.

Oral Administration

Carbenicillin in gelatin capsules was given at a dose of 500 mg. to healthy fasting volunteers. Serum samples were taken at ½, 1, 2, 4, and 6 hours after administration of the dose, and urine was collected over the period 0 to 6 hours. No carbenicillin (that is, less than 1 μg./ml.) was detected in the serum, and the quantity present in the urine amounted to less than 1% of the dose administered. It would appear, therefore, that carbenicillin is not absorbed to any appreciable extent when administered orally.

Intramuscular Administration

Carbenicillin was administered by intramuscular injection to groups of healthy adult volunteers as single doses of 250 mg., 500 mg., and 1,000 mg. The 250-mg. dose was given in a volume of 1 ml. of water for injection, and the 500-mg. and 1,000-mg. doses were dissolved in 2 ml. of water. Blood specimens were collected ½, 1, 2, 4, and 6 hours after administration, and the urine was collected during the six-hour period after dosing. Results of these studies are summarized in Table IV.

TABLE IV.—*Mean Serum Concentrations of Carbenicillin After Intramuscular Injection in Adult Volunteers*

No. of Subjects	Dose (mg.)	Serum Concentration (μg./ml.)						% of Dose Excreted in Urine over 0–6 hrs.
		½-hr.	1 hr.	2 hrs.	3 hrs.	4 hrs.	6 hrs.	
10	250	5·9	7·9	5·7	2·6	< 2·0	< 2·0	71
9	500	13·7	17·7	13·2	—	2·0	< 2·0	82
16	1,000	21·6	25·3	22·1	—	10·9	3·7	84

Mean serum peak levels of 7.9 μg./ml. carbenicillin were obtained one hour after administration of the 250-mg. dose, and these declined to <2 μg./ml. after four hours. Increasing the dose to 500 mg. resulted in serum concentrations twice as high as those obtained with the 250-mg. dose, but these declined to barely detectable concentrations after four hours. Impressive results were obtained with the 1,000-mg. dose, the mean serum concentrations being greater than 20 μg./ml. for the first two hours after injection, falling to 10.9 μg./ml. at four hours.

The amounts of carbenicillin excreted in the urine during the first six hours after injection were 71% of the dose with the 250-mg. dose, 82% of the 500-mg. dose, and 84% of the 1,000-mg. dose, producing average carbenicillin concentrations in the urine of 1,000 to 2,000 μg./ml. with the 500-mg. dose and 2,000 to 4,000 μg./ml. with the 1,000-mg. dose.

The effect of probenecid was investigated in a crossover study in which 10 subjects were given 1,000 mg. carbenicillin by the intramuscular route. One week later the same subjects took oral probenecid (1 g.) 10 hours and one hour before receiving 1,000 mg. intramuscular carbenicillin. The administration of probenecid resulted in a marked increase in the carbenicillin serum concentrations (Table V and Fig. 3) and in a significant reduction in the rate of elimination of carbenicillin from the serum.

Chromatographic examination of the urine after intramuscular administration of carbenicillin showed no evidence of the formation of biologically active metabolites.

Although carbenicillin is primarily of interest for its activity against *Ps. pyocyanea,* the compound is active against a wide range of bacteria, including *E. coli* and various ampicillin-resistant proteus species, and it seems probable that intramuscular doses of 500 to 1,000 mg. carbenicillin might be successfully used to attain serum, tissue, and urine concentrations adequate for the treatment of infections caused by these organisms. On the other hand, the activity of carbenicillin against *Ps. pyocyanea* is such that inhibitory concentrations of carbenicillin with respect to this particular pathogen are not likely to be achieved in serum and tissue by intramuscular

TABLE V.—*Effect of Probenecid on Serum Levels and Urinary Excretion of Carbenicillin in Healthy Adult Volunteers. (Carbenicillin Dose 1 g. by Intramuscular Injection)*

Without probenecid	10	26·8	29·4	22·2	10·8	3·3	84

* 1 g. 1 hour and 10 hours before administration of carbenicillin.

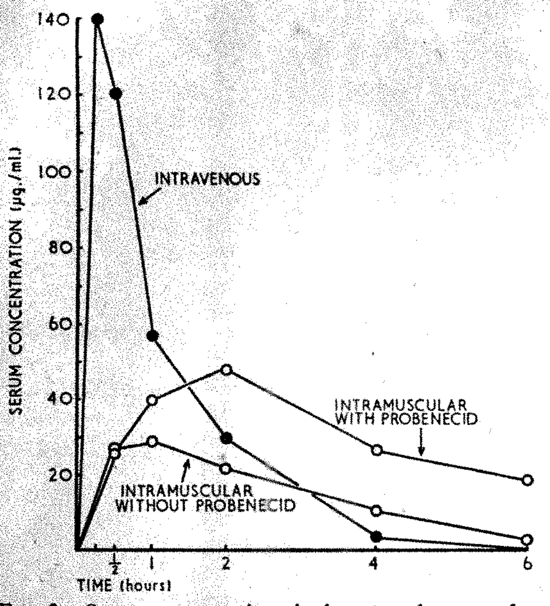

FIG. 3.—Serum concentrations in human volunteers after intramuscular and intravenous administration of 1 g. of carbenicillin.

dosing. Nevertheless, the urine concentrations attained after intramuscular administration of carbenicillin are greatly in excess of the minimum inhibitory concentrations of the drug against *Ps. pyocyanea*, and the results of clinical trials indicate that 1,000 mg. of carbenicillin given four times daily by the intramuscular route may be adequate for the treatment of acute urinary tract infections due to this organism.

Intravenous Administration

Two subjects were given 1,000 mg. of carbenicillin by slow intravenous injection. The penicillin was dissolved in 10 ml. of sterile water for injection and administered over a period of three minutes. Serum concentrations of greater than 100 µg./ml. carbenicillin were obtained during the first half-hour after administration of the compound, although at four hours only trace amounts of carbenicillin were detected (Table VI and Fig. 3).

From the bacteriological studies, concentrations of carbenicillin in the order of 100 µg./ml. would be expected to inhibit the growth of most strains of *Ps. pyocyanea*, but in view of the rapid elimination of the drug from the body frequent administration would probably be necessary. In practice the results of clinical studies have shown that, for the treatment of septicaemia, tissue infections, and chronic urinary tract infections due to *Ps. pyocyanea*, carbenicillin should be given at a dose of 1 g. hourly by the intravenous route, preferably together with probenecid, in order to maintain inhibitory concentrations in the body.

TABLE VI.—*Serum Concentration of Carbenicillin After Intravenous Administration of 1 g.*

Subject	Serum Concentration (µg./ml.)					
	¼-hr.	½-hr.	1 hr.	2 hrs.	4 hrs.	6 hrs.
A	140	127	60	28	3·7	<3·0
B	140	114	55	32	4·4	<3·0

Summary

Carbenicillin is a new semisynthetic penicillin active against *Pseudomonas pyocyanea*. The compound shows a broad spectrum of activity against Gram-positive and Gram-negative bacteria and is active against strains of *Proteus vulgaris, Pr. rettgeri*, and *Pr. morganii*, which are typically resistant to ampicillin. With a very heavy inoculum of *Ps. pyocyanea* marked inhibition of growth occurs with carbenicillin at 25 to 50 µg./ml., but some very scanty growth may persist even at concentrations of 125 to 250 µg./ml. With a slightly smaller inoculum complete inhibition of growth occurs at 25 to 50 µg./ml. Carbenicillin is bactericidal and is not highly bound to serum protein. Carbenicillin is not absorbed when given by mouth, but high concentrations of the drug are obtained in serum after intramuscular or intravenous administration, and these levels are increased and are more prolonged with concomitant use of probenecid. Carbenicillin is excreted in high concentration in the urine.

We thank Dr. J. H. C. Nayler for preparing the carbenicillin used in these studies, Mr. D. Lawson for the photograph in Fig. 1, and Mrs. Eleanor Fairclough for technical assistance.

Prophylaxis and Therapy for *Pseudomonas aeruginosa* Infection with Carbenicillin and with Gentamicin

R. J. JONES,* M.SC., PH.D.; E. J. L. LOWBURY,* M.A., D.M., F.C.PATH.

Brit. med. J., 1967, 3, 79–82

The polymixins have for many years been the antibiotics of choice for the treatment of infection with *Pseudomonas aeruginosa*; but although they are active against all strains in vitro their clinical value has been limited. In the treatment of burns, local applications were found to have prophylactic value (Jackson, Lowbury, and Topley, 1951; Cason and Lowbury, 1960), but systemic administration has been less effective in the control of invasive infection (Tumbusch *et al.*, 1961; Kefalides *et al.*, 1964; Jones, Jackson, and Lowbury, 1966).

Two new antibiotics with promising activity against *Ps. aeruginosa* have recently been developed. Gentamicin (Weinstein *et al.*, 1963) is a broad-spectrum antibiotic which is reported to have good activity in vitro and therapeutic value in patients infected with *Ps. aeruginosa* (Bulger, Sidell, and Kirby, 1963; Klein, Eickhoff, and Finland, 1964; Barber and Waterworth, 1966). Carbenicillin (B.R.L. 2064) is a semi-synthetic penicillin with moderate activity in vitro against *Ps. aeruginosa.*

In this paper we report studies which showed that parenteral administration of carbenicillin and of gentamicin protected burned mice against invasive infection with strains of *Ps. aeruginosa*. The use of carbenicillin in the treatment of patients whose burns were infected with *Ps. aeruginosa* was studied in a small controlled trial.

Materials and Methods

Assessments of Prophylaxis and Therapy

Protection of burned mice against virulent strains of *Ps. aeruginosa* was assessed by methods described elsewhere (Jones and Lowbury, 1965; Jones *et al.*, 1966). Mice were anaesthetized with ether and given full-skin-thickness burns of approximately 5% of the body surface. Three hours after burning, the surface of the burned area was inoculated with approximately 700 million viable cells of *Ps. aeruginosa.*

Treatment with antibiotics was started, firstly, immediately after burning and before inoculation with *Ps. aeruginosa,* to assess their prophylactic value, and, secondly, 24 hours, 48 hours, and 72 hours after inoculation with *Ps. aeruginosa,* to assess the therapeutic value of the antibiotics. A group of six burned infected mice was included in each experiment as a control.

All mice were examined and weighed daily for a period of 14 days. Bacterial cultures on blood agar and cetrimide agar (Brown and Lowbury, 1965) were obtained on alternate days from burns of mice receiving the highest dosage of antibiotics. Necropsy examinations, which included cultures of heart blood, were made on all mice that died.

Strains of Ps. aeruginosa

Two strains, B4 and P14, which had previously been found virulent for the mouse and which differed in serotype, were used in the experiments. The saline suspensions inoculated on burns were prepared from overnight cultures on nutrient agar. Strains rendered resistant to the antibiotics by habituation in vitro (see below) were also tested.

Antibiotic Treatment

The antibiotics were administered, in separate experiments, by intraperitoneal and intramuscular routes. Two injections were given each day (at 10 a.m. and 5 p.m.) for five days, and one injection (full dosage) on days 6 and 7. Dosage was adjusted in relation to the surface area of the animal, estimated from its weight (Bushby, 1964; Butler and Richie, 1960); on this basis approximately 660 and 1,000 mg. of carbenicillin per kg. per day and 12 and 18 mg. of gentamicin per kg. per day were selected for treatment of mice. Carbenicillin was also tested at lower dosages (approximately 330 and 160 mg./kg./day). Colistin sulphomethate was tested at 40 and 400 mg./kg./day; in earlier experiments (Jones *et al.*, 1966) approximately 80 mg./kg./day of colistin sulphomethate had been used.

Levels of antibiotics in the serum of burned and of unburned mice were obtained from assays on pooled serum of groups of three mice taken at intervals of half-hour, three hours, and six hours after intraperitoneal administration of the antibiotics. The assay was by a tube dilution method with a sensitive strain of *Staphylococcus aureus* (Oxford) for gentamicin and of *Ps. aeruginosa* (Elsworth) and (in earlier tests) of *Staph. aureus* (Oxford) for carbenicillin; a strain of *Ps. aeruginosa* (B4) was also used for assay of colistin sulphomethate. The inoculum was 0.02 ml. of a 1/1,000 dilution of a broth culture of the test organism.

A group of mice was also treated prophylactically with methicillin (5,000 mg./kg./day).

Mixed Infection with Penicillinase-producing Organisms

Mixed infections with *Ps. aeruginosa* and *Staph. aureus* are common in burned patients. To determine whether the presence of penicillinase-producing bacteria interferes with the protective value of carbenicillin against *Ps. aeruginosa,* prophylaxis with the antibiotic was assessed in groups of mice infected by the application to burns of *Ps. aeruginosa* (B4 and P14) and a similar inoculum of a penicillinase-producing strain of *Staph. aureus* (1899).

Antibiotic Sensitivity Tests

Strains of *Ps. aeruginosa* were tested for sensitivity to carbenicillin, gentamicin, and colistin sulphomethate by a tube dilution method; the inoculum was 0.02 ml. of 10^{-3} dilutions of overnight broth cultures in nutrient broth containing doubling dilutions of the antibiotic.

Tests for Inactivation of Carbenicillin by Penicillinase

Penicillinase-producing strains of *Staph. aureus* (B/4324 and B/4327) were inoculated in nutrient broth containing carbenicillin (1,000 µg. per ml.); after incubation for two hours at 37° C. the culture was filtered through a Hemmings filter and tested for residual activity by diffusion from Heatley cylinders on blood agar plates seeded with sensitive strains of *Staph. aureus* (Oxford strain) and *Ps. aeruginosa* (strain B4) (Lowbury, Topley, and Hood, 1952).

---

* The M.R.C. Industrial Injuries and Burns Research Unit, Birmingham Accident Hospital.

Tests for Production of Penicillinase by Ps. aeruginosa

Strains of *Ps. aeruginosa*, including those which had acquired resistance to carbenicillin in vitro, were tested for diffusible penicillinase by estimation of residual penicillin after incubation for two hours of fresh cultures in infusion broth containing 100 µg. per ml. of carbenicillin and 100 units per ml. of penicillin G; filtrates were tested on blood-agar plates seeded with *Staph. aureus* (Oxford strain).

Habituation of Ps. aeruginosa to the Antibiotics

Strains of *Ps. aeruginosa* (B4 and P14) were tested for the emergence of resistant variants by serial subculture in tubes of broth containing ranges of doubling dilutions of carbenicillin and gentamicin; daily subcultures were made to new test ranges from the tubes containing the highest concentration of antibiotics which did not inhibit growth. Tests for stability of resistance acquired in these strains were made by subculture in the absence of the antibiotics.

Results

Sensitivity of Strains.—Table I shows the distribution of minimal inhibitory concentrations (M.I.C.) of carbenicillin, gentamicin, and colistin sulphomethate for 80 miscellaneous strains of *Ps. aeruginosa*, mostly from burns, and 26 typed strains, including 14 distinct serotypes. With one exception, the M.I.C.s of carbenicillin were in the range 32–128 µg./ml.; the M.I.C. of gentamicin was in the range 1 to 4 µg./ml., and that of colistin sulphomethate was from 1 to 8 µg./ml. Two strains used in the studies on mice (B4 and P14) were inhibited by carbenicillin at M.I.C.s of 64 and 128 µg./ml. and by gentamicin at 0.5 and 4 µg./ml.; both strains were inhibited by colistin sulphomethate at an M.I.C. of 4 µg./ml. The M.I.C.s of methicillin for two strains of *Ps. aeruginosa* were 1,000 and 4,000 µg. per ml.

TABLE I.—*Sensitivity of 106 Strains of Ps. aeruginosa to Three Antibiotics*

Antibiotic	Strains	No. of Strains Inhibited by M.I.C. (µg./ml.)								Total Strains

* Elsworth strain.

Inactivation of Carbenicillin by Penicillinase.—Penicillinase-producing strains of *Staph. aureus* were found to destroy the activity of carbenicillin against both *Staph. aureus* and *Ps. aeruginosa.*

Prophylaxis against Ps. aeruginosa.—The results summarized in Table II show that mice infected with *Ps. aeruginosa* (B4 and P14) by application of the organism to fresh burns were protected against invasion and fatal septicaemia when courses of prophylactic treatment with carbenicillin were given. Intraperitoneal and intramuscular injections were equally effective. Similar treatment with gentamicin prevented invasion and death when the infecting strain was B4, but it had a smaller effect against P14, which was less sensitive to gentamicin. Colistin sulphomethate, on the other hand, showed little or no prophylactic effect at any of the three dosage levels tested, including those reported earlier (Jones *et al.*, 1966), and methicillin was also ineffective. The burns of the infected mice in all series appeared red, with some areas of moisture. Heavy growths of *Ps. aeruginosa* were isolated from swabs taken from the burns of infected mice, whether treated with antibiotics or not. At necropsy the infected mice showed pathological changes described elsewhere (Jones *et al.*, 1966), including usually the presence of *Ps. aeruginosa* in blood from the heart.

Significance tests.—The results of experiments marked with the same footnote symbol are grouped together; they were compared with the results in untreated mice infected with the same strain of *Ps. aeruginosa*. * $\chi^2 = 48{\cdot}4$, $P < 0{\cdot}001$ (strain B4). † $\chi^2 = 24{\cdot}5$, $P < 0{\cdot}001$ (strain P14). ‡ $\chi^2 = 42{\cdot}3$, $P < 0{\cdot}001$ (strain B4). § $\chi^2 = 3{\cdot}8$, $P = 0{\cdot}05$ (strain P14).

Blood Levels of the Antibiotics.—The concentration of antibiotics in the pooled serum from groups of burned and unburned mice bled at half an hour, three hours, and six hours after administration of a single dose are shown in Table III; inhibitory levels of carbenicillin and of gentamicin were found in the first sample. In mice which had recently received 5% burns the serum level of gentamicin in relation to dosage was high compared with that of carbenicillin. In tests with unburned mice, serum levels half an hour after injection of gentamicin were much lower. No difference between burned and unburned mice was found in serum levels of carbenicillin. The serum from mice treated with colistin sulphomethate did not contain detectable levels of the antibiotic.

TABLE III.—*Assays of Antibiotics in Serum of Mice After Intraperitoneal Administration*

Antibiotic	Mice	Dosage (mg./kg./dose)	Concentration of Antibiotics in Serum (µg./ml.)		
			½ Hour after Dose	3 Hours after Dose	6 Hours after Dose

	B4	72	4	2	67
Centamicin	B4	24	0	6	0
	B4	48	4	8	33
	B4	72	4	2	67

*Dosage.—Carbenicillin: 1,000 mg./kg./day, IP, for 7 days. Gentamicin: 12 mg./kg./day, IP, for 7 days.

Use of Carbenicillin and Gentamicin on Mice with Burns Already Infected.—When courses of treatment with carbenicillin or gentamicin were started 24 hours after inoculation of burns with *Ps. aeruginosa* (strain B4) the survival rate was as high or almost as high as it was in the series given prophylaxis (Table IV). When longer delays occurred before treatment was started a larger proportion of mice died with infection.

Prophylaxis by Carbenicillin against Ps. aeruginosa in the Presence of Penicillinase-producing Staphylococci.—In mice protected with carbenicillin (1,000 mg./kg./day) there were three deaths out of 12 with invasive *Ps. aeruginosa* infection when a penicillinase-producing *Staph. aureus* was also inoculated on the burn (Table V); in those inoculated with *Ps. aeruginosa* alone and similarly protected there were two deaths out of 33. *Ps. aeruginosa,* but not *Staph. aureus,* was found in the blood culture of the mice which died.

TABLE V.—*Prophylaxis by Carbenicillin in Burned Mice Infected with Ps. aeruginosa and a Penicillinase-producing Staph. aureus*

Treatment Group	Infecting Strains of		No. of Mice which			*Ps. aeruginosa* in Blood Culture at Necropsy
	Ps. aeruginosa	*Staph. aureus*	Died	Survived	% Deaths	
No antibiotic	B4	1899	3	3	50	3
	P14	1899	5	1	83	4
Carbenicillin	B4	1899	1	5	17	1
	P14	1899	2	4	33	2

Habituation of Ps. aeruginosa to Carbenicillin and Gentamicin in vitro.—Strains of *Ps. aeruginosa* showed moderate increases of resistance on repeated subcultures in subinhibitory concentrations of the antibiotics. For strain B4, increases in M.I.C. from 64 to 1,024 μg./ml. of carbenicillin and from 0.5 to 4 μg./ml. of gentamicin were obtained; increases in resistance of strain P14 were from 128 to 2,048 μg./ml. carbenicillin and from 4 to 64 μg./ml. of gentamicin. The strain rendered resistant to carbenicillin grew as small colony variants which produced oxidase and grew on cetrimide agar, but showed poor fluorescence; unlike the sensitive parent strain, they produced a diffusible penicillinase which inactivated benzylpenicillin. There was no reversion to sensitivity on repeated subculture in the absence of carbenicillin. The strains rendered resistant to gentamicin were also of small colony type, but they produced moderate amounts of fluorescein; reversion to sensitivity on subculture did not occur.

Tests with burned mice (Table VI) showed that variants resistant to carbenicillin were avirulent, while those which were resistant to gentamicin appeared to have diminished virulence. Unlike the sensitive parent strains, they were not found on the burns of mice later than on the day of inoculation.

TABLE VI.—*Mortality of Burned Mice Infected with Strains of Ps. aeruginosa Rendered Resistant in vitro to Carbenicillin and to* Gentamicin

Infecting Strain of *Ps. aeruginosa*	Sensitivity Pattern	No. of Mice which			*Ps. aeruginosa* in Blood Culture at Necropsy
		Died	Survived	% Deaths	
B4	Sensitive to carbenicillin and gentamicin ..	87	33	72·5	86

	Resistant to carbenicillin	0	6	0	—
	Resistant to gentamicin	3	3	50	2

Administration of Carbenicillin to Patients with Burns

To assess the value of carbenicillin in the treatment of burns infected with *Ps. aeruginosa* a controlled therapeutic trial was started. On the first appearance of *Ps. aeruginosa* in cultures from one or more burns, patients were allocated alternately to treatment and control groups. Those in the treatment group were given a seven-day course of carbenicillin (in adults 1 g. six-hourly by intramuscular injection, with probenecid 0.5 g. six-hourly). Local treatment of the burns was with a cream containing 0.5% silver nitrate and 0.1% chlorhexidine, or with penicillin cream, or with neomycin chlorhexidine tulle gras; in previous experience none of these methods had been effective in removing *Ps. aeruginosa* from burns. The burns were swabbed at changes of dressings (usually every two or three days) and examined for *Ps. aeruginosa* and other bacteria as described elsewhere (Lowbury, 1960; Brown and Lowbury, 1965).

Because of recent success in prophylaxis against *Ps. aeruginosa* in this unit, especially with silver nitrate compresses and cream (Cason *et al.,* 1966), the number of patients available for study in this trial has been very small.

An interim analysis showed that 10 out of 23 burns in nine patients treated with carbenicillin lost *Ps. aeruginosa* during or immediately after the course of treatment. Out of 23 burns in the seven patients of the control series, only one showed the loss of *Ps. aeruginosa* in a corresponding period of time. There was a significant difference in the proportion of burns from which *Ps. aeruginosa* was eliminated in the two groups of the trial ($\chi^2 = 6.3$, $P < 0.02$).

In addition to these patients two others were treated with carbenicillin because the heavy colonization of their burns with *Ps. aeruginosa* was thought to be causing severe clinical infection (not septicaemic). One patient was a man aged 62 with burns of the legs (approximately 12% of the body surface, mostly partial skin loss); he was admitted from another hospital 14 days after injury with cellulitis of both legs, and was severely ill, with confusion, rapid irregular pulse, signs of bronchitis, intestinal distension, and loose green stools; blood examination showed a haemoglobin level of 9.9 g./100 ml., a leucocytosis (W.B.C. 18,000, polymorphonuclear neutrophils 87%, lymphocytes 9%, monocytes 4%), E.S.R. 60 mm./hour (Wintrobe), and a blood urea of 135 mg./100 ml. A heavy growth of *Ps. aeruginosa* was isolated from the burns in pure culture. Blood cultures were sterile, but the severity of the patient's illness was considered to be associated with infection by *Ps. aeruginosa.*

During a course of treatment with carbenicillin (continued for three weeks) the patient's condition improved rapidly, and *Ps. aeruginosa* disappeared from six out of eight of the burns. Assays of carbenicillin in the serum while the patient had renal insufficiency showed 16 μg./ml. at one hour, 32 μg./ml. at three hours, and 64 μg./ml. at five hours after the injection of a dose of the antibiotic. At a later stage, when the kidney function had recovered, serum levels of carbenicillin were lower (16 μg./ml. at three hours and at six hours after administration of the drug).

Another patient with burns heavily colonized with *Ps. aeruginosa* and having normal kidney function was given carbenicillin for seven days with probenecid (2 g./day). Assays of the drug in the patient's serum showed levels of 48 μg./ml. at one hour, 32 μg./ml. at three hours, and 32 μg./ml. at five hours after a dose of carbenicillin. Two of the three burns were cleared of *Ps. aeruginosa* and one showed a reduction in their numbers during the course of treatment.

Sensitivity of Ps. aeruginosa to Carbenicillin during the Trial

In two of the eleven patients treated with carbenicillin *Ps. aeruginosa* isolated after the course of treatment was more resistant (M.I.C. 265 μg./ml.) than the strain initially present (M.I.C. 64 μg./ml.). Tests on the "resistant" strains from one of these patients showed no penicillinase production. The phage type of the more resistant variant was the same as that of the strain present before treatment.

Discussion

Infection of burns with *Ps. aeruginosa* is commonly acquired in hospital. Usually the organism remains localized, colonizing slough and exudate, with no ill effect except some interference with skin grafts and consequent delays in healing (Jackson *et al.*, 1951). Occasionally it causes invasive infection with cellulitis, invasion of the walls of small blood vessels, and in some cases septicaemia (Fraenkel, 1906; Jackson *et al.*, 1951; Rabin *et al.*, 1961; Teplitz *et al.*, 1964a, 1964b; Sevitt, 1964).

This complication is often fatal, and antibiotic treatment is likely to fail even when it removes the organism from the lesions, because of irreparable damage which has occurred by the time invasion is recognized (Jones *et al.*, 1966). For this reason it is important that high-risk cases should receive effective prophylaxis. Silver nitrate compresses (Moyer *et al.*, 1965; Cason, Jackson, Lowbury, and Ricketts, 1966) and isolators (Cason *et al.*, 1966) are useful barriers against contamination, but they are not invariably successful. A second line of defence for such cases is systemic prophylaxis by antisera or by antibiotics.

The two antibiotics studied in this paper, like the specific antisera recently described by Jones *et al.* (1966), protected mice against invasion by *Ps. aeruginosa.* All strains of *Ps. aeruginosa* which were tested were at least moderately sensitive to carbenicillin and highly sensitive to gentamicin; variants which became resistant to carbenicillin on habituation in vitro had lost virulence for mice, and an apparent reduction in virulence was found also in gentamicin-resistant variants obtained in this way.

Gentamicin is more active than carbenicillin in vitro against *Ps. aeruginosa,* and smaller doses are recommended for treatment. Carbenicillin on the other hand, though only moderately active in vitro, was more successful than might have been expected in its prophylactic action against *Ps. aeruginosa* in mice.

In burned patients treated with carbenicillin and probenecid the highest blood levels were rarely higher than the minimal inhibitory concentration for the infective strains; nevertheless, a significantly larger proportion of burns were cleared of *Ps. aeruginosa* in patients treated with carbenicillin than in the untreated controls. This clearance was associated with persistence of or replacement by other organisms in the burns.

Study on a larger series of patients is needed for an assessment of this unexpectedly favourable result; meanwhile it is possible that the local application of silver nitrate and chlorhexidine, though ineffective by itself, may have contributed to the effect of systemic treatment with carbenicillin against *Ps. aeruginosa.*

None of the patients studied in the trial had septicaemia; a considerably higher dosage would undoubtedly be required for successful treatment in such cases.

Gentamicin was less effective than carbenicillin in prophylaxis against the less sensitive of the two strains tested, though the dosage was sufficient to give inhibitory serum levels in the mice; gentamicin (unlike carbenicillin) was found in much higher concentration in the serum of mice which had recently been burned than in unburned mice. The combined use of carbenicillin and gentamicin, like that of gentamicin and ampicillin (Bulger and Kirby, 1963), might be expected to have a synergistic action and deserves study. Both agents may be useful in the protection of patients treated with cytotoxic drugs and other high-risk cases.

The failure of colistin sulphomethate to protect mice was associated with an absence of detectable colistin in the serum of mice receiving treatment with the antibiotic. Kitamoto, Fukaya, and Honma (1962) have also reported an absence of colistin in the serum of treated mice, though the antibiotic was detected in the kidneys at necropsy. In burned patients, however, appreciable blood levels and evidence of some therapeutic value from very large dosage of colistin sulphomethate have been reported (Jones *et al.*, 1966).

Summary

A series of 106 strains of *Pseudomonas aeruginosa* were sensitive in tube dilution tests to gentamicin (M.I.C. 1 to 4 μg./ml.) and moderately sensitive to a new semisynthetic penicillin, carbenicillin (M.I.C. 32 to 128 μg./ml.); one strain was found to be more sensitive to carbenicillin. Carbenicillin was inactivated by the penicillinase of *Staph. aureus.*

Groups of mice were infected by inoculation of small burns with two strains of *Ps. aeruginosa*; about 70% of the mice infected with these strains died with septicaemia. Courses of treatment with carbenicillin gave serum levels in burned or unburned mice up to 128 μg./ml., and the mice were completely protected against both strains. Gentamicin gave peak blood levels in recently burned mice of 64–128 μg./ml. but lower levels (4–8 μg./ml.) in unburned mice; gentamicin protected the animals against the more sensitive strain of *Ps. aeruginosa* only (M.I.C. 0.5–1 μg./ml.). Similar results were obtained with treatment by carbenicillin or by gentamicin, starting at the time of infection or 24 hours later. In most experiments colistin sulphomethate gave no evidence of protection.

A small controlled trial in progress on patients with burns has shown that *Ps. aeruginosa* was removed from a significantly larger proportion (10/24) of burns in patients treated with carbenicillin and probenecid than in untreated controls (1/23). The highest blood levels of carbenicillin (48–64 μg./ml.) were in the same range as its minimal inhibitory concentration against the infecting strains.

A strain of *Ps. aeruginosa* which acquired resistance to carbenicillin in vitro was converted to a small colony form and showed a loss of virulence for burned mice. In a similar experiment with gentamicin the resistant variants were also small colony forms, but retained some virulence for mice.

We wish to thank Beecham Research Laboratories for supplies of BRL 2064 and information about the antibiotic, Roussel Laboratories for supplies of gentamicin, our technical colleagues for their co-operation, and the surgeons and nursing staff of the Burns Unit for permission to use clinical data. We also thank Dr. M. T. Parker for phage-typing strains of *Ps. aeruginosa.*

Observations on Urinary White Cell Excretion Before and After Surgery

R. M. LINDSAY,* M.B.; B. LUNAN,† M.B.; J. McGEACHIE,‡ M.D., M.C.PATH.
A. L. LINTON,§ M.B., M.R.C.P.ED., M.R.C.P.GLASG.

Brit. med. J., 1967, 3, 83–85

Quantitative determination of the cells excreted in the urine has until recently been regarded as a cumbersome and time-consuming procedure (*Lancet*, 1961). Houghton and Pears (1957) attempted to simplify the technique, and McGeachie and Kennedy (1963) described a method of semi-quantitative cell counting which was suitable for routine use yet was much more accurate than the ordinary wet-film technique. In the course of a recent study of renal function after surgery (Lindsay *et al.*, 1965) it was observed that there was a considerable difference between urinary white cell excretion rates before and after surgery in many patients, so further investigation of this was undertaken.

Patients and Methods

A group of 138 patients (81 males and 57 females) undergoing surgery in a general surgical ward were studied. The surgical procedures ranged from ligation of varicose veins to total colectomy, and any patient having direct interference with the genitourinary tract (including catheterization) was excluded. All had general anaesthesia. Preoperatively each patient was questioned about urinary tract symptoms, and any definite history of urinary tract infection or catheterization was recorded. Semi-quantitative cell counts, as described by McGeachie and Kennedy (1963), were performed on clean midstream specimens of urine, the examination being carried out within two hours of collection. In all cases the urinary cells were stained by the method of Prescott and Brodie (1964) to differentiate between white cells and tubular cells. Each patient was seen again 24 to 48 hours after operation; urinary symptoms were recorded and the cell count was repeated. Urine volumes were recorded, and patients who excreted less than 600 ml. of urine between 24 and 48 hours after operation were excluded.

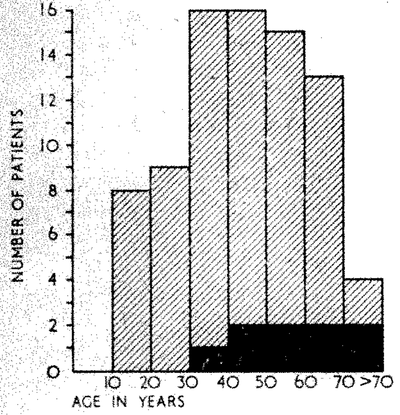

FIG. 1

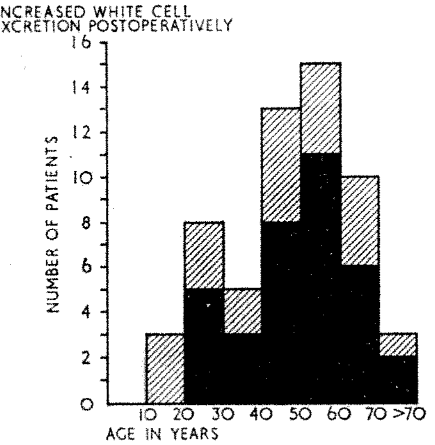

FIG. 2

FIG. 1.—Age distribution of 81 males—general surgical group. FIG. 2.—Age distribution of 57 females—general surgical group.

In 62 consecutive patients in the group urine was sent for bacteriological examination before and after operation. Delays in transmission of specimens to the laboratory were minimized, and bacterial counting was done by the method described by McGeachie and Kennedy (1963).

In a further group of 14 patients (4 males and 10 females) fully quantitative cell counts were done before and after operation. These were carried out on accurate three-hour urine collections kept acid to litmus and refrigerated during the collection. The cells were counted by the method of Houghton and Pears (1957) after staining by Prescott and Brodie's method (1964). Bacterial counts were performed concurrently on all of these specimens.

A further group of 46 patients (23 males and 23 females) aged 9 to 80 years undergoing minor surgery on the ear, nose, or throat were studied in addition to the 152 general surgical patients.

Results

The staining technique of Prescott allows the counting of white blood cells, red blood cells, tubular cells, and squamous epithelial cells. A considerable difference was found between rates of excretion preoperatively and postoperatively only for white cells; no further reference will be made to the other types of cell counted.

In the general surgical group, of the 81 males only 5 (6%) had a urinary white cell count above the normal range preoperatively, and 9 (11%) had an abnormal cell count postoperatively, including all the five originally abnormal. Of the 57 females of this group 6 (10.5%) showed an abnormal cell count preoperatively, but 35 (61%) were abnormal postoperatively.

As shown in the Table, seven of the nine males with an increased white cell excretion postoperatively gave a history of urinary tract infection or of catheterization. The relation of history of urinary infection or catheterization in the females is also shown in the Table. The age distribution of all patients with an abnormal postoperative white cell count is given in Figs. 1 and 2.

Bacterial counts were carried out in 39 consecutive male patients. No bacterial count of more than 100,000 organisms

Correlation Between Past History and an Increased Urinary White Cell Excretion Postoperatively in 81 Males

per ml. was obtained preoperatively and only one postoperatively. This was associated with an abnormal cell count. In the 38 male patients who were negative bacteriologically two abnormal cell counts were obtained postoperatively, associated with negative cultures. Both patients had been given antibiotics since the day of operation.

Of the 23 consecutive female patients in whom bacterial counts were done four had above 100,000 organisms per ml. preoperatively and five postoperatively (the latter five includes the previous four), all of the positive postoperative counts being associated with abnormal urinary white cell excretion. A further five patients had increased white cell excretion postoperatively, but negative culture; three of these five had been receiving antibiotics since operation.

In the 14 patients in whom fully quantitative cell counts were done the upper limit for normal white cell excretion rate was chosen as 400,000 cells per hour; this is higher than most authors suggest (Addis, 1926; Rofe, 1955; Houghton and Pears, 1957; Hutt *et al*., 1961). Of the 10 female patients so examined only one had an abnormal cell excretion rate preoperatively, and this was associated with a bacterial count in excess of 100,000 organisms per ml. (Fig. 3). Postoperatively there were five cases with abnormal white cell excretion, four of which were associated with positive bacterial counts. Of the four male patients in whom fully quantitative cell counts were done none showed increased white cell excretion either before or after operation (Fig. 4).

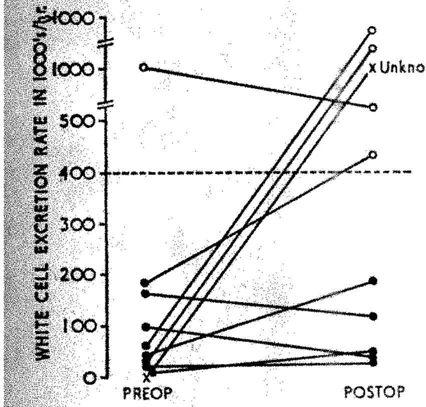

FIG. 3

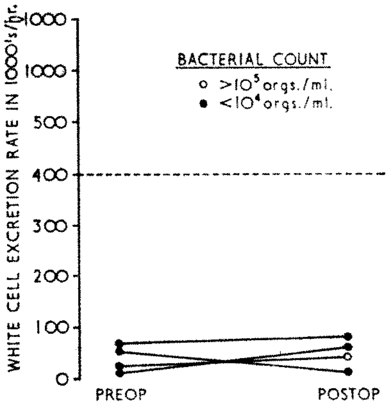

FIG. 4

FIG. 3.—White cell excretion rates and bacterial counts in 10 females undergoing general surgery. FIG. 4.—White cell excretion rates and bacterial counts in four males undergoing general surgery.

In the additional group of 46 patients who were studied while undergoing minor surgery of the ear, nose, or throat, none of the 23 males had positive cell counts or bacterial counts at any time. Of the 23 females four showed an abnormal rise in urinary white cell excretion after surgery, and three of them gave a past history of urinary tract infection.

In the whole group of 198 patients only four females complained of urinary symptoms postoperatively, and in each case this was associated with increased white cell excretion. There was no evidence that type of surgery or duration of anaesthesia had any influence on the numbers of patients showing increased white cell excretion or significant bacteriuria.

Discussion

This study has shown that in many patients undergoing surgery unrelated to the genitourinary system there is a marked rise in urinary white cell excretion postoperatively. Furthermore, this phenomenon was noted in 61% of the females studied, but in only 11% of the males. The rise in the females is highly significant ($P<0.001$). The increased white cell excretion rate was confirmed in a small number of cases by fully quantitative cell counts, and bacterial counting suggested that in most cases it was accompanied by significant bacteriuria (>100,000 organisms per ml.). There did not appear to be any relation between type of surgery or duration of anaesthesia and the increased white cell excretion. Almost all of the male patients who showed increased white cell excretion postoperatively had a history of previous urinary tract infection or of catheterization; this relation was less definite in the females.

With unexpected findings of this nature the accuracy of the techniques used must always be questioned. The increased white cell excretion was detected by the semi-quantitative technique of McGeachie and Kennedy (1963), which does not take into account the volume of urine passed. It is obviously possible that oliguria might give false-positive results, but all oliguric patients were excluded from the study. Almost all of the patients studied passed more than 1 litre of urine between 24 and 48 hours after operation, and at this urine volume the upper limit of normal for the McGeachie and Kennedy method corresponds to a urinary excretion of 350,000 white cells per hour; the authors themselves established that the method gives few false-positive results. Fully quantitative cell counts confirmed the findings, 400,000 white cells excreted per hour being taken as the upper limit of normal, as is generally accepted (Hutt *et al*., 1961; Kennedy *et al*., 1964). The use of the differential staining techniques described by Prescott and Brodie (1964) ensured that the cells counted were white cells and not the otherwise indistinguishable small renal tubular cells.

Prescott (1966) suggested that the normal urinary white cell excretion rate for males is much lower than for females, and it might be that this would explain the sex difference noted in the present study. However, almost none of the males showed any rise at all in white cell excretion rates, while the vast majority of females who are recorded as showing positive cell counts were very clearly above the upper limit of normal even for females. The fact that we have observed this marked sex difference would militate against another possible explanation of postoperative rise in white cell excretion, the use of analgesics, which may increase urinary cell excretion. In addition, Prescott (1965) showed that the increased cell count after analgesic ingestion was due to a rise in renal tubular cell excretion, not leucocytes. Finally, bacterial counting strongly suggests that the cases in this series which showed a rise in white cell excretion very often had significant bacteriuria also.

Houghton and Pears (1957) studied variations in the rate of leucocyte excretion in the urine of normal subjects; they found no differences with age or sex, and only slight differences with posture and time of collection. On the other hand, Prescott (1966) showed a marked sex difference, considerable variation from patient to patient, and even from time to time in the same patient. It must be remembered, however, that these differences were all within the normal range. Other documented reasons for increases in urinary leucocyte excretion to above the normal range are urinary tract infections, during fever in pneumonia (Goldring, 1931), in pregnancy (Elden and Cooney, 1935), and after vigorous exercise (Roberts, 1935). None of these situations was applicable to the present study.

The cause of the abnormalities recorded in this paper remains uncertain. The marked sex difference, the fact that males showing a rise in white cell excretion postoperatively almost all had a previous history of urinary tract infection, and the association of pyuria and significant bacteriuria all suggest that the phenomenon is related in some way to urinary tract infection. It might be suggested that pooling of urine in the bladder postoperatively contributed to the significant bacteriuria or even to the pyuria, but the collections were not made on the first postoperative day, and it is unlikely that this would explain the marked sex difference. It is highly unlikely that over 60% of apparently normal women had latent urinary tract infection, but perhaps the changes we have observed are in some way related to the unknown cause underlying the increased susceptibility of the female to urinary tract infection.

Summary

Semi-quantitative urinary white cell counts were performed in 198 patients before and after surgery. A significant rise in white cell excretion rates was found in 61% of the females but in only 11% of the males. The results were confirmed in a further group of patients by means of fully quantitative cell counts, and bacterial counting showed that this pyuria was often associated with significant bacteriuria. The possible significance of these findings is discussed.

Use of Diazepam in Treatment of Severe Convulsive Status Epilepticus

MAURICE J. PARSONAGE,* M.B., B.SC., F.R.C.P., D.C.H. ; JOHN W. NORRIS,† M.B., M.R.C.P.

Brit. med. J., 1967, **3**, 85–88

During the past three years diazepam (Valium) has been used extensively, both in Europe and in the U.S.A., chiefly as a tranquillizing agent but also as an anticonvulsant (Gross and Kaltenbäck, 1963 ; Goldstein, 1963 ; Trolle, 1965). Until recently there have been comparatively few published accounts of its use in the treatment of status epilepticus. One of the earliest was that of Naquet *et al.* (1965), and others were by Gastaut *et al.* (1965), Iborra (1965), Piqué and Henking (1965), Revol *et al.* (1965), Bamberger and Matthes (1966), and Lombroso (1966).

In common with chlordiazepoxide (Librium) and nitrazepam (Mogadon), diazepam is a member of the benzodiazepine group of drugs. It has tranquillizing, muscle relaxant, and anticonvulsant actions. In experimental animals its depressant action has been found to act mainly on structures in the limbic system, including the hippocampus, amygdala, and reticular formation (Randall *et al.*, 1961 ; Morillo, 1962 ; Hernández-Peón *et al.*, 1964 ; Schallek *et al.*, 1964 ; Schallek and Kuehn, 1965). It has also been shown that seizures arising in the amygdala in rats can be prevented by the prior administration of this drug (Eidelberg *et al.*, 1965). The literature relative to this subject has been extensively reviewed by Boyer (1966).

We report here the use of diazepam in the treatment of nine severe cases of convulsive status epilepticus.

Material and Methods

There were four males and five females, whose ages ranged from 11 to 53 years (Table I). In practically all cases the epilepsy was of long standing and probably associated with gross brain damage. In at least six of the nine patients there was a probable source of seizure discharge in one or other frontal lobe, and in several instances there had been previous episodes of convulsive status epilepticus.

After admission to hospital all patients were at first given diazepam in 10-mg. doses (1 ampoule), either intravenously or intramuscularly as required. When it became apparent that the drug had only a transient action it was given as an intravenous infusion, initially in a dosage of 100 mg. in 1 litre of physiological saline. Latterly, intravenous infusions of 100 mg. of the drug in 500 ml. of saline were given.

All patients had the usual nursing care, with particular attention to respiratory function and to fluid and electrolyte balance. Whenever it was thought necessary tracheostomy and controlled respiration were employed. Tests for liver function were carried out in Cases 5–9. In most of the patients E.E.G. studies had previously been carried out with resulting location

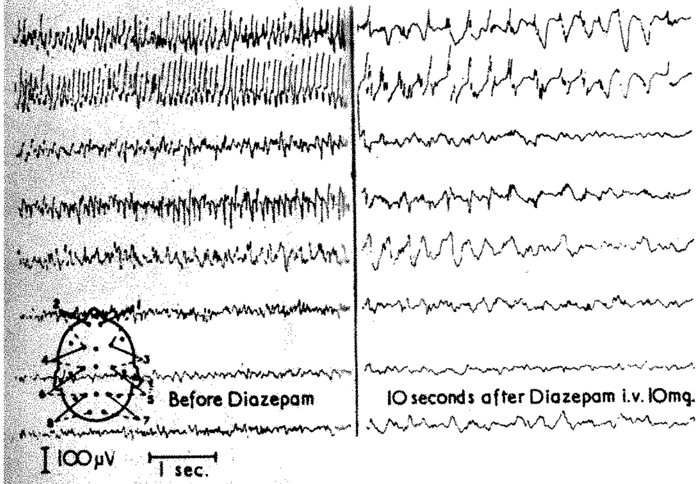
of sources of seizure discharge, but further recordings were performed as often as possible during treatment of the status epilepticus.

Results

The results are summarized in Table II. Immediate control of seizures was obtained in seven of the nine patients. In most of these the effect of diazepam was very rapid, being evident within 10–20 seconds of the beginning of the injection (see Illustration). In Cases 1 and 6 the control was not enduring, and it was deemed advisable to resort to the use of other methods of treatment (intravenous paraldehyde, etc.).



Showing the rapid interruption of seizure discharge in the E.E.G. after the intravenous administration of diazepam (Case 9).

In Case 2 treatment with diazepam was abandoned at an early stage because of initial uncertainty concerning the effects of giving the drug in high dosage. For the same reason a similar policy was adopted in Case 3, and the seizures were eventually suppressed only with great difficulty with the aid of curarization and controlled respiration, together with the combined administration of phenobarbitone and phenytoin in high dosage. This patient was subsequently found to be severely demented.

In Cases 4 and 8 complete control of seizures was obtained after giving 10 mg. of diazepam intramuscularly. Thereafter it was given as an intravenous infusion over a period of three days while the patients were in the intensive care unit. When the seizures recurred the following day they were easily controlled with paraldehyde.

Case 7 was remarkable for the fact that control of seizures was not obtained even after the administration of 190 mg. of diazepam. The patient, a backward boy aged 12, remained in a comatose state and eventually died at the end of five weeks, presumably as a result of severe brain damage. His seizures had continued almost uninterrupted for nearly three weeks, despite curarization and controlled respiration and finally the institution of hypothermia.

In Case 9, after the intravenous administration of only 17.5 mg. of diazepam, the blood pressure fell to 70/50 from a level on admission of 105/70. In the belief that this might be due to diazepam, the drug was discontinued and intravenous paraldehyde given. However, as the seizures remained uncontrolled and the blood pressure had become stabilized at a level of 90/50, a further 131.5 mg. of diazepam was given as an intravenous infusion in conjunction with controlled respiration. Though control of seizures was soon obtained in this way, without any further fall in blood pressure, the patient remained in a comatose state and died two days later. At necropsy an infarction of the left cerebral hemisphere was found, adjudged to be some four to five days old. It was confined to the cortical territory of the middle cerebral artery, two branches of which were found to be occluded by fibrin clot. A similar clot was attached to the intima on the dorsal wall of the abdominal aorta. In the inferomedial portion of the right temporal lobe there was gliosis of the white matter adjacent to the amygdaloid nucleus and satellitosis of cortical neurones in the deeper laminae. In this area many small arteries showed collagenous change, and similar changes were found in the corresponding area in the left temporal lobe but without any associated gliosis. There was no evidence of hypoxic damage or incisural sclerosis in either temporal lobe.

It seems likely that the degenerative vascular changes seen in the right temporal lobe in this fatal case were related to the epilepsy, particularly since they were associated in life with a local slow wave and sharp wave abnormality in the E.E.G., indicating local neuronal hyperexcitability. In view of the estimated age of the left cerebral infarction it appeared very probable that it had occurred before diazepam therapy was begun, though its relation to the onset of the status epilepticus remains problematical. Furthermore, it also seems very likely that the blood pressure had already begun to fall before treatment was started, since this patient is known to have had a blood pressure of at least 150/90 in the past.

TABLE II.—*Summary of Results*

Case No.	Previous Treatment	Treatment with Diazepam				Supplementary Treatment	Total Duration of Status (days)	Final Result
		Day Treatment Begun	Maximum Dose in 24 hours	Total Amount Given	Effect			
1	Paraldehyde on 1st day	2nd	30 mg.	30 mg. over 24 hours	Temporary control	Paraldehyde	6	Ultimate control. Residual mild left hemiparesis
2	Paraldehyde (i.m.) and phenytoin (i.v.) for 3 days	3rd	30 ,,	30 mg. over 24 hours	Temporary control	Controlled respiration. Thiopentone (i.v.)	3	No change
3	Paraldehyde 10 ml. (i.m.) on 1st day	1st	40 ,,	70 mg. over 2 days	Unsatisfactory control	Controlled respiration. Curarization. Phenobarbitone and phenytoin	8	Severe dementia
4	None	1st	150 ,,	335 mg over 7 days	Temporary control i.m. but complete when given i.v.	None	7	No change
5	None	1st	160 ,,	170 mg. over 3 days	Satisfactory control	Paraldehyde	17	Persistent elevation of serum alkaline phosphatase level
6	None	1st	200 ,,	900 mg. (approx.) over 7 days	Temporary control	Controlled respiration. Intracarotid amylobarbitone	4–5	No change
7	Paraldehyde (i.m.) on 1st day	2nd	140 ,,	190 mg. over 3 days	None	Controlled respiration. Paraldehyde. Hypothermia	20	Severe brain damage. Died
8	None	1st	150 ,, (approx.)	350 mg. over 7 days	Complete control	None	2–3	No change
9	None	1st	149 mg.	169 mg. over 2 days	Satisfactory control	Controlled respiration. Paraldehyde	3	Hypotension. Cerebral infarction. Died

Side-effects

A hypnotic effect was evident to some degree in most cases when the dosage of diazepam exceeded 10 mg. intravenously. In higher dosage semicoma usually supervened, but this was always transient. There were, however, no abnormal mental changes as described by Femi-Pearse (1966).

A tendency to the development of tolerance became evident when continuous intravenous infusions of diazepam were employed in dosages ranging from 300 to 500 mg. spread over a period of two to three days. This was particularly striking in Case 6, in which the drug appeared to lose its effect on the seizures, and this could not be restored when intermittent intravenous injections were given subsequently.

There were no cases in which respiratory suppression occurred as a result of the administration of diazepam. No abnormalities of the peripheral blood picture or of renal function were encountered.

Evidence of abnormal liver function was found in three patients (Cases 5, 8, and 9). In the first of these there had been an illness six months previously characterized by fever, lymphadenopathy, and hepatosplenomegaly which was thought to be due to a toxic reaction to methoin therapy. After the administration of just over 100 mg. of diazepam there was found to be a rise in the serum aspartate aminotransferase level to 62 units, while that of the serum alkaline phosphatase had risen to 19.6 K.A. units. The serum alanine aminotransferase level remained normal. The serum aspartate aminotransferase level returned to normal within a week, whereas the alkaline phosphatase level has remained raised (30–40 K.A. units). In Case 8 a rise of the serum aspartate aminotransferase level to 64 units was found after two days' treatment with approximately 250 mg. of diazepam, but this had returned to normal at the end of a week. In Case 9 the serum aspartate aminotransferase level had risen to 68 units on the second day of treatment, but the patient did not survive long enough for any further estimations to be made.

In no case was there any evidence of tissue necrosis at the site of injection.

Discussion

In all our patients except one (Case 7) the immediate suppressant effect of diazepam on convulsive seizures was clearly evident. This was seen, however, only when the drug was given intravenously, and we were not able to confirm the observation of Naquet *et al.* (1965) that status epilepticus was terminated within minutes of the intramuscular injection of diazepam. It is noteworthy that Piqué and Henking (1965) used the intravenous route in all their cases, whereas Iborra (1965) and Gastaut *et al.* (1965) used both the intravenous and the intramuscular routes. However, since the two routes were often used in the same patient it is difficult to conclude which was the more effective.

In our first three patients diazepam was given in relatively small doses intermittently lest dangerous side-effects should occur, and also after other treatment had proved to be ineffective; even so, the effect of diazepam was appreciable, and satisfactory control of seizures might have been achieved if larger doses had been given. In the remaining six patients treatment with diazepam was begun earlier and much larger doses were given by continuous infusion. In four of these good control of seizures was obtained, though in Case 6 it was only temporary and other measures had to be used.

Case 7 was remarkable for the fact that neither the administration of diazepam nor any of the other measures used had any obvious effect on the seizures. This patient was a mentally retarded boy aged 12 who had had previous episodes of status epilepticus and who lapsed into a severely demented state before death finally occurred, despite eventual interruption of his continuous epileptic state.

Though respiratory depression has always been regarded as a possible side-effect of diazepam, there have apparently been very few reports of this ever having occurred to a dangerous degree. Indeed, Femi-Pearse (1966) has reported the use of as much as 720 mg. daily in the treatment of tetanus without ill-effect. Gastaut *et al.* (1965) quote the case of a 9-month-old baby whose hemiclonic status was stopped by giving 6 mg. of diazepam intramuscularly but whose breathing then became shallow. There appeared, however, to be a slow spontaneous return later to normal respiration. In none of our cases was there any indication of respiratory depression that could be attributed to diazepam administration, though we felt it was advisable always to be prepared for such a complication.

The findings in Case 9 have been described in detail in view of the possibility that the administration of diazepam may have played some part in causing the hypotension and cerebral infarction. We have, however, given reasons why we think this unlikely. It would appear, therefore, that in none of our cases was there any evidence of depression of vital centres, despite the infusion of comparatively large amounts of diazepam.

With doses of more than 10 mg. a hypnotic effect was observed in most of our cases, and this had to be taken into account when assessing conscious levels. The development of tolerance was also a notable feature; this usually became evident within 24 hours of beginning an intravenous infusion, and appeared to be related to the total dosage given. Furthermore, when tolerance had occurred in this way it apparently could not be obviated by afterwards giving the drug intermittently. Side-effects such as mental disturbances and diuresis (Femi-Pearse, 1966) or ataxia and diplopia (Payne and Ishmael, 1963; Trolle, 1965) were not observed in our cases.

It is doubtful if the abnormal results of the liver function test in three of our cases could be attributed to treatment with diazepam. In the first of these (Case 5) such abnormalities could not certainly be dissociated either from previous anticonvulsant therapy or from the presumed toxic reaction to methoin in which there had been involvement of the reticuloendothelial system. Unfortunately, liver function tests had not been carried out at the time of this illness. In the other two patients (Cases 8 and 9) the raised serum aspartate aminotransferase levels could have been due to secondary effects of the status epilepticus, such as severe muscular contraction and widespread tissue hypoxia.

On the basis of the results of treatment in our small series of cases of severe convulsive status epilepticus we feel that diazepam has a useful and important part to play in the control of such states. It appears to be an effective agent, rapid in its action and apparently free from serious side-effects. It provides a useful alternative method to treatment with barbiturates and paraldehyde. Indeed, there is much to be said for regarding it as the treatment of choice in the management of all types of status epilepticus at the present time.

Summary and Conclusions

The results of the treatment with parenteral diazepam (Valium) in a series of nine cases of severe convulsive status epilepticus are reported.

In seven out of the nine patients immediate rapid control of seizures was obtained. In two of these control was only temporary, but in one of them this may have been due to inadequate dosage. Treatment by intravenous infusion was found to be the most effective method.

No serious side-effects occurred which could with certainty be attributed to treatment with diazepam.

Two patients died. In one case this was apparently due to vascular occlusion causing extensive cerebral infarction. In the second all measures used failed to control the seizures and death occurred as a result of severe brain damage.

It is concluded that intravenous diazepam therapy has a useful and important part to play in the treatment of severe convulsive status epilepticus.

We would like to acknowledge our indebtedness to Roche Products Limited for financial assistance and to Dr. John Garrod for his interest and helpful advice. We are grateful to Dr. Denis Harriman for the necropsy findings in Case 9 and to Dr. Kenneth Exley for help with the manuscript. We should also like to thank Mrs. Grace Murray for help in preparing the illustrations and Miss Hilary Stevens for typing the manuscript.

Intermittent Haemodialysis: Insertion and Care of the Silastic-Teflon Cannula

G. J. A. CLUNIE,* M.B., F.R.C.S., F.R.C.S.ED.; A. M. MARTIN,† M.B., M.R.C.P.ED.
B. NOLAN,‡ M.B., F.R.C.S., F.R.C.S.ED.

Brit. med. J., 1967, **3**, 88–90

The exteriorized Silastic-Teflon arteriovenous cannula introduced by Quinton, Dillard, Cole, and Scribner (1962) has simplified vessel access in patients requiring intermittent haemodialysis. Cannula complications still cause considerable discomfort and inconvenience to the patient, however, and account for much of the medical and surgical attention required. In the renal unit of the Royal Infirmary, Edinburgh, where this system of cannulation has been in regular use since October 1964, a number of modifications in the technique of insertion and aftercare of the cannulae have been made, and these are described in this report.

Insertion

All procedures were carried out in a surgical theatre. The nondominant arm was used wherever possible, the vessels cannulated being the radial artery close to the wrist and a forearm vein of adequate size. Leg cannulae were used primarily in three men whose work involved repetitive arm movements, and secondarily in one woman after loss of arm sites. The posterior tibial artery immediately proximal to the medial malleolus and the long saphenous vein at a slightly higher level provided satisfactory leg vessels (Fig. 1). Many patients requiring intermittent dialysis showed extensive atherosclerosis, and patency of and adequacy of flow through the ulnar or dorsalis pedis arteries were checked before ligation of the vessels used for cannulation.

The technique used was similar to that described by Hegstrom, Quinton, Dillard, Cole, and Scribner (1961) and by Quinton *et al.* (1962). Both local and regional block anaesthesia proved satisfactory, but general anaesthesia was used in children or where multiple procedures were performed. Care was taken to avoid placing the subcutaneous loop over bone, since this caused early erosion of the overlying skin. Longitudinal incisions were used over the artery to allow adequate exposure, but the wounds were closed in at least two layers to bury the cannulae as deeply as possible. Transverse incisions were used for vein cannulation (Clark and Parsons, 1966), the security of closure and avoidance of later erosion through the wound compensating for lack of access in the more superficially placed vein. A single vertical incision proved satisfactory where artery and vein lay close together and at approximately the same level, and was particularly useful in the leg.

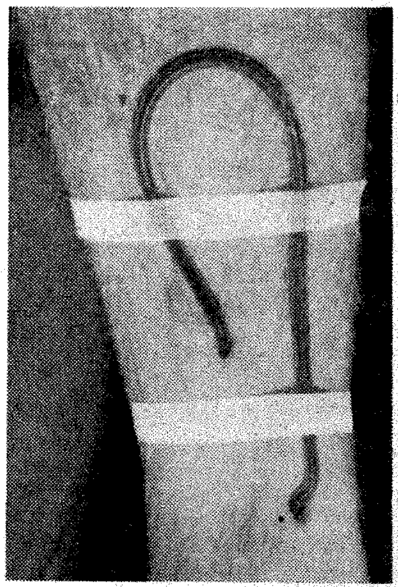

FIG. 1.—Case 1. Leg cannulae 18 months after insertion.

The Teflon tip used was the largest compatible with the original vessel diameter, and vein tips were always at least one

† Registrar, Renal Unit, Royal Infirmary, Edinburgh 3.
‡ Consultant Surgeon, Royal Infirmary, Edinburgh 3.

size larger than arterial, in order to avoid pressure gradients in the shunt. Crimp and joint rings at the Silastic-Teflon junction were used initially (Fig. 2A), but as the internal rings tended to ulcerate they were replaced by extending the distal vessel ligature around the cannula. A single break shunt (Fig. 2B) with a long venous Silastic segment (Sevitt, Comty, Rottka, and Shaldon, 1964) was used, and the original Teflon-to-Teflon external bayonet junction was replaced by the insertion of a large vessel tip between the Silastic ends. The making and breaking of this junction was later made easier by discarding the external rings. No accidental leaks have occurred with this simplified system. External metal stabilizers caused skin reactions and were therefore replaced by Micropore Tape (Minnesota Mining and Manufacturing Company).

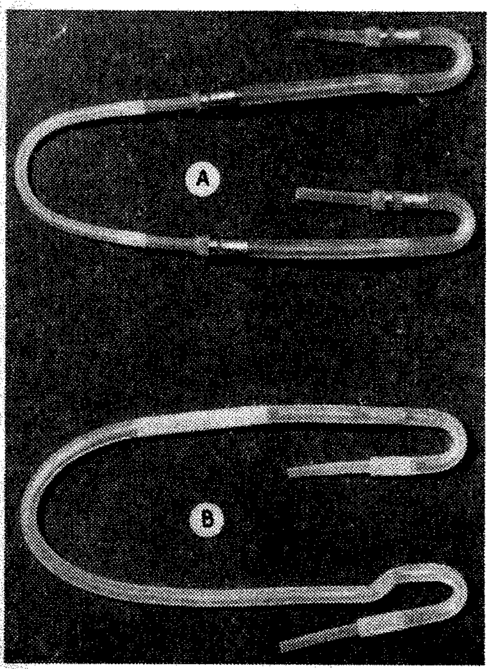

FIG. 2.—A, Original form of shunt with crimp and joint rings, short Silastic segments, and an external Teflon loop. B, Simplified form of shunt without rings, a long venous Silastic segment, and a single external Teflon break.

Movement of the cannulated limbs was reduced postoperatively by elevation in a sling for two days in the case of the upper limb, and by confinement to bed for 10 days in that of the lower limb. Splints were not used. Skin sutures were removed at two weeks. Wound healing was appreciably faster and more satisfactory when the patient's general condition was good, or had been improved by blood transfusion and peritoneal dialysis (Pendras and Smith, 1966). Use of the shunt was avoided within seven days of insertion so far as was possible, but earlier dialysis did not compromise the life of the cannulae.

Aftercare

The daily dressing and toilet described by Quinton *et al.* (1962) was not used, and, unless there was leakage between dialysis, the dressings were left undisturbed until the time of the next treatment. All patients showed skin reactions to cleansing agents used at the time of treatment, and a simple mechanical toilet with swabs soaked in normal saline was found to be more satisfactory. Bacteriological swabs were taken before and after each dialysis from the cannula exit wounds and the exposed ends of the external Teflon break. Light dressings and bandages were used to allow free use of the limb, the proximal end of the loop being loosely covered to allow frequent inspection by the patient for clotting.

Results

The cumulative experience in 11 patients over 12.1 patient-years between 1 October 1964 and 30 September 1966 is shown in the Table. Patients under treatment for less than three months and those who were treated for short periods before renal transplantation were not included in the series. Cannulae functioning on 30 September 1966 were thought to have failed on that day in order to estimate mean cannula survival times. The mean arterial cannula life was 7.6 months and the venous 7.3 months.

* Shunts functioning on 30 September 1966.

The two main limiting factors were clotting and infection. Forty-eight episodes of clotting occurred in 8 of the 11 patients, leading to loss of cannulae on 10 occasions. One of these cannulae also showed evidence of infection. In the majority of patients episodes of clotting were due either to an external cause such as kinking or compression of the shunt or to exposure to cold, as in a man with leg cannulae who stood in a river for four hours while fishing. Episodes of spontaneous clotting occurred fairly often in a smaller group of patients, and appeared to be due either to hypovolaemia secondary to serum protein deficiency or to a phlebitis of obscure origin. Declotting was easily carried out with the methods described by Hegstrom *et al.* (1961) and by Pendras and Smith (1966) if the patient reported within three hours of the episode, particularly if there

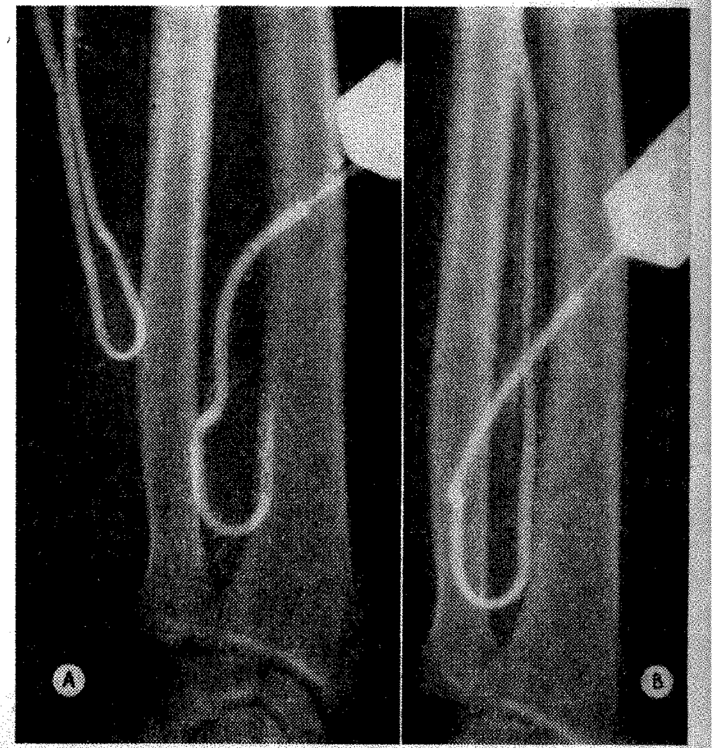

FIG. 3.—A, Arteriogram performed after routine declotting procedures. This cannula has been clotted for 24 hours. B, Further arteriogram after streptokinase infusion: the small clot at the vessel tip was easily dislodged by suction, and flow restored.

was an obvious mechanical cause. If flow was still unsatisfactory after attempted declotting, clots were occasionally dislodged or vessel spasm was overcome by the slow infusion of a solution of 20,000 international units of heparin in 500 ml. of saline. Angiograms were performed by the injection of 3 to 4 ml. of 60% Urografin via the open end of the cannula (Fig. 3) in resistant cases. An attempt was then made to dissolve visualized clot by the injection of 250,000 units of streptokinase (Kabikinase) in 2 ml. of sterile water into the cannula, which was clamped for 30 minutes. Flow was restored by this procedure on four of the seven occasions on which it was used. Where declotting was not successful, one limb or occasionally both limbs of the shunt were replaced. Anticoagulants were used systemically after recurrent episodes of clotting, and were particularly valuable where there was evidence of phlebitis.

Twenty episodes of infection occurred in 8 of the 11 patients, being secondary to skin erosion over the venous loop on seven occasions. Nine of these infections led to loss of cannulae. The causative organism was *Staphylococcus aureus*, except in two cases where a β-haemolytic streptococcus was isolated. Septicaemia secondary to cannula infection occurred in two patients, and was successfully treated by antibiotics without loss of the cannulae. Nasal, throat, and perineal swabs were taken before insertion of cannulae and at intervals thereafter. Attempts were made to eradicate nasal and skin carriage of staphylococcus, but persistent carriers were treated with lincomycin (Lincocin), cloxacillin (Orbenin), or methicillin (Celbenin) from the time of insertion of cannulae for periods of two to four weeks. If infection became established and persisted in spite of antibiotic therapy, the cannulae were removed and another limb was cannulated next day under antibiotic cover. In four patients with infected arterial cannula wounds persistent bleeding occurred, and was found to be due to false aneurysm formation. Bleeding was controlled by proximal ligation of the vessel and removal of the cannula. A more detailed analysis of these infections, with particular reference to phage typing and the source of the organisms, will be presented elsewhere.

Summary

Two years' experience with the Silastic-Teflon arteriovenous cannula system in the management of patients with chronic renal failure by intermittent haemodialysis is reported. The mean arterial cannula survival time was 7.6 months and the venous survival time 7.3 months. Careful attention to a number of apparently minor points during insertion improved cannula survival. The two limiting factors in cannula life were clotting and infection. Declotting was usually achieved if the patient attended within three hours. If flow was unsatisfactory after using standard declotting procedures angiography was performed and streptokinase infused into the cannula. Flow was restored in four out of seven cannulae by this method. The causative organism was *Staphylococcus aureus* in almost all the cases of infection. Antibiotics were used both prophylactically and therapeutically, but cannula removal and replacement in another limb was necessary in 9 out of 20 cases of infection.

We wish to thank Dr. J. S. Robson and Professor M. F. A. Woodruff for permission to report on cases under their care, and for their advice and encouragement; Dr. R. W. Tonkin for the bacteriological investigations; Dr. D. J. Sinclair and Dr. T. A. S. Buist for the angiographic studies; and Mr. A. Patterson for the photographs.

Prevention of Urinary Infection by Means of Closed Drainage into a Sterile Plastic Bag

W. A. GILLESPIE,* M.D., F.C.PATH., F.R.C.P.I., M.R.C.P.; G. G. LENNON,† M.B., CH.M., F.R.C.O.G., M.M.S.A.

Brit. med. J., 1967, **3**, 90–92

If urinary infection is to be avoided when indwelling catheters are used, bacteria must be prevented from entering the bladder or destroyed soon after they enter. Infection through the catheter may be prevented by drainage into a closed sterile container. Passage of bacteria between catheter and urethral wall (an important route of infection in females) may be diminished by immobilizing the indwelling catheter. Application of these measures, together with disinfection of the urethra and bladder when catheters were inserted, reduced the postoperative urinary infection rate in gynaecological patients from 97 to 13% (Gillespie, Lennon, Linton, and Slade, 1962, 1964).

Drainage bottles containing formalin, which were used in these studies, were troublesome to prepare. We report here the results obtained with the use of closed sterile plastic bags instead of bottles.

Materials and Methods

Meredith‖ urine drainage bags were used after 1 January 1965 (see Photograph). The drainage tube, which is sealed into the bag, ends in a valve, a flat collapsible plastic tube. Any increase of pressure in the bag closes the valve and prevents reflux of urine into the tube.

The patients, all of whom had uninfected urine initially, underwent gynaecological operations similar to those in the previous investigation and were treated in the same ward. Their bladders were drained by indwelling Foley catheters for four days after operation; during the next few days most patients were catheterized intermittently, between one and six times in all, to remove residual urine. Except for the substitution of plastic bags for bottles, the postoperative treatment was the same as before (Gillespie *et al.*, 1964); Foley catheters were immobilized by fitting plastic sponge collars which were smeared twice daily with chlorhexidine (Hibitane) obstetric cream. Chlorhexidine was also used to disinfect the urethra and bladder every time a catheter was inserted.

Meredith plastic drainage bag with non-return valve.

Results

The results of the present and previous trials are summarized in Table I. The first results with plastic bags were disappointing; more than half the patients became infected. The fault, however, was probably not in the valve or bag. Culture of urine samples taken simultaneously from the tube above the valve and from the bag showed that bacteria were rarely present in the bag before they appeared in the tube. It seemed likely that bacteria entered the catheter when the drainage tube was disconnected to change the bag when it became full. The point of disconnexion, where the tube joined the catheter, was under the bedclothes, near the patient, and therefore liable to heavy contamination. Moreover, plastic tubes lack elasticity and are difficult to connect and disconnect neatly. Accordingly, several precautions were taken to prevent entry of bacteria when changing bags. The plastic drainage tube was cut short a few inches above the bag and connected to the catheter by a sterile rubber tube. When the bag became full it was detached from the lower end of the rubber tube, a less heavily contaminated site and farther from the patient. The infection rate fell to 17% (Table I).

Though the modifications which caused this improvement probably would not be practicable in a busy ward, the results showed the danger of infection by bacteria entering when full bags were detached from the catheter. The next stage in the trial, therefore, was to use one bag for each patient, as a reservoir, and never change it. The drainage tube was connected to the catheter before the patient left the theatre. When the bag became full it was emptied through an opening distal to the valve, made by cutting off a corner opposite the point of entry of the drainage tube (see Photograph). The bag was tilted and the urine poured into a pail containing phenolic disinfectant. The corner of the bag was then sealed with waterproof tape until the next emptying. Seventy-four patients were treated by reservoir drainage; 17 (23%) became infected (Table I).

Study of the responsible bacteria suggested that most infections occurring during the period of full precautions were caused by self-infection, whereas previously, with open drainage and no special precautions, cross-infection was very common. During the initial period there were many mixed infections by *Klebsiella, Proteus vulgaris, Pr. rettgeri, Pr. mirabilis,* and *Escherichia coli* (Table I).

Many strains of *Klebsiella* and *Proteus* were resistant to several antibiotics and probably indicated cross-infection (Gillespie, Linton, Miller, and Slade, 1960). When the infection rate fell after the introduction of precautions, most of the resistant bacteria disappeared. Most of the infections that still occurred were caused by *E. coli* and *Pr. mirabilis,* which probably came from the patients themselves. Support for this belief was obtained by testing *Pr. mirabilis* isolates by Dienes's method (Dienes, 1946; Kippax, 1957). Of 12 isolates which were examined, 10 were distinct from each other. Hence most infections during the period of full precautions were probably due to a fault in the management of the catheter and not in the method of drainage. The recent preponderance of *Pr. mirabilis* may be due to the fact that it is less sensitive than *E. coli* to chlorhexidine (Table II).

Discussion

Several methods may be used to prevent infection during indwelling catheterization. All should incorporate some form

TABLE II.—*Minimum Inhibitory Concentrations of Chlorhexidine for the Strains of E. coli and Pr. mirabilis from Urine Infected During the Use of Plastic Reservoir Drainage Bags*

* Some infections were mixed.

of closed sterile drainage. Disposable sterile plastic bags are convenient, but many that have appeared on the market are unsatisfactory, since though they are sterile initially they become contaminated during use (Roberts, Linton, Pollard, Mitchell, and Gillespie, 1965). The bag should remain closed during use and should be designed to prevent reflux of urine into the drainage tube. This is important, since small numbers of bacteria may pass from the urethra to the bladder and thence to the bag, where they may multiply and, if reflux is allowed, re-enter the bladder in large numbers. The longer the period of drainage the greater the chance of infection arising in this way. It would be dangerous to place a disinfectant in a non-rigid receptacle, since compression might force it back into the bladder. Kunin and McCormack (1966) described the use of a reservoir drainage bag without a valve. However, it is difficult to compare their results with ours, because few of their patients were gynaecological. Moreover, most of their patients received antimicrobial drugs, whereas none of ours did. Several drainage bags with valves have appeared on the market. We have found the valve of the Meredith bag to be the most efficient of those we have seen. In laboratory tests in which the bag was filled with contaminated urine it was impossible to force bacteria back through the valve by compressing the bag. However, when a partly filled bag was laid gently on the floor, and not compressed, a slow reverse flow could sometimes be detected. In practice, such slow leakage would be opposed by the flow of urine, which also would oppose the movement of motile bacteria.

Perhaps the greatest risk of infection during closed drainage is by bacteria that gain access to the catheter when the receptacle is detached because it is full. It follows that if reflux can be avoided it should be safer (and more economical) to use the bag as a reservoir and empty it periodically without detaching it from the drainage tube and catheter. The infections that occurred in our patients during drainage into reservoir bags were attributable, for the most part, to invasion of the bladder by bacteria, especially *Pr. mirabilis,* which passed along the outside of the catheter, probably because they were rather insensitive to the chlorhexidine that was used to exclude bacteria from this route.

Patients and nurses preferred the plastic bags to the glass drainage bottles, which ambulant patients found cumbersome. It remains to be seen how efficient the bags will be during longer periods of drainage and after prostatectomy, when it is sometimes necessary to irrigate the bladder.

Summary

Sterile disposable plastic bags with non-return valves were used for closed drainage of urine after gynaecological operations. It was found best to use the bag as a reservoir, joining it to the catheter before the patient left the theatre and not detaching it until the indwelling catheter was removed four days later. The bag was emptied periodically through an opening distal to the valve. Of 74 patients who were treated in this way, 17 (23%) became infected. This was a slightly greater rate of infection than that observed during a previous period when bottles containing formaldehyde were used as receptacles. The infections probably were not attributable to faults in the drainage bag or valve, but to bacteria which passed from the urethra into the bladder outside the catheter, despite the precautions taken to exclude them.

We thank Eschmann Bros. and Walsh Ltd. for a supply of Meredith drainage bags.

Medical Memoranda

Methaqualone Addiction and Delirium Tremens

Brit. med. J., 1967, **3**, 92–93

Four cases of addiction to the non-barbiturate hypnotic methaqualone have been reported (Madden, 1966). The probability that these patients were physically dependent on methaqualone has been disputed (Martin, 1966) because of failure to show an abstinence syndrome. We now document another case, which was associated on withdrawal with the clinical syndrome of delirium tremens characteristic of the barbiturate–alcohol type of dependence.

CASE REPORT

A 47-year-old married man had suffered from rheumatoid arthritis since 1947. In turn he took increasing quantities of barbiturates (developing macrocytic anaemia), of an analgesic mixture containing phenacetin (developing nephrocalcinosis and renal tubular acidosis), of thalidomide (developing peripheral neuropathy), and later chloral hydrate.

For four years before admission he had been taking increasing doses of methaqualone, and for at least some months before admission had taken neither alcohol nor any other drug. In the weeks prior to being admitted (January 1966) he was taking 60 150-mg. tablets of methaqualone daily.

He was found unconscious one evening (two days before admission) and his stocks of methaqualone were destroyed. Next evening he was restless and confused, and complained of seeing strangers in dark corners of the room.

On admission he was in delirium with obvious tremor. He was anxious and restless, and had visual hallucinations of which he was afraid. His temperature was 100° F. (37.8° C.), with brisk reflexes, and blood pressure 130/70. The liver was palpable 2 cm. below the costal margin. A combination of promazine 600 mg. daily, phenobarbitone 1 g. daily, and paraldehyde 10 ml. intramuscularly as required for states of agitation was only partially successful in controlling his restlessness and led to intoxication (with slurred speech, ataxia, and nystagmus). However, the administration of thioridazine (Melleril) in doses up to 800 mg. daily, starting on the fourth day, resulted in dramatic improvement and rapid recovery.

DISCUSSION

Delirium tremens has not only been produced experimentally by withdrawal of addicting doses of barbiturates (Isbell *et al.*, 1950) and alcohol (Isbell *et al.*, 1955), but has now been recorded also with chloral hydrate, paraldehyde, glutethimide

(Doriden), methyprylone (Noludar), ethchlorvynol (Arvynol), and meprobamate (Miltown, Equanil) (*Brit. med. J.*, 1964; Wood and Flippin, 1965). The clinical features described in these studies correspond very closely with those found in our patient.

Methaqualone has been shown to be a potent hypnotic (Parsons and Thomson, 1961; Duchastel, 1962). It is marketed in the United Kingdom as Melsedin, and in combination with diphenhydramine as Mandrax. It is sold in the U.S.A. as Quaalude. Melsedin was described as a non-barbiturate hypnotic that "produces natural sleep" and to which neither tolerance nor addiction had been attributed. The makers have told us that they now know of four cases of addiction, in addition to the one reported here, three of the patients concerned having a history of addiction also to barbiturates or alcohol (J. W. Buckler, personal communication, 1966).

Mandrax is claimed to have an action that is "quite different from that of the barbiturates and almost all other hypnotics." No addiction had been reported to the makers, who pointed out (February 1966) that their product had been generally available for only four months (A. L. Macnair, personal communication, 1966).

Though recent neurophysiological methods of investigation of the action of drugs on sleep (Oswald and Thacore, 1963; Oswald and Priest, 1965) may eventually clarify the relevance of withdrawal syndromes, at present the clinical picture of delirium tremens is one means of categorizing the pharmacological action of psychotropic drugs. Apart from the remarkable experiments of Isbell and his colleagues it seems that at present we must rely on those patients who abuse their drugs to assist us in this classification.

We are grateful to Professor J. A. Strong for permission to report this case, and to the manufacturers for the information mentioned above.

Thrombocytopenic Purpura in Patient with Autoimmune Haemolytic Anaemia, Successfully Treated with Mercaptopurine

Brit. med. J., 1967, 3, 93–94

Before the introduction of corticosteroids in 1949 splenectomy and blood transfusions were the only well-established treatments for autoimmune haemolytic anaemia (Dacie, 1954; Schwartz and Dameshek, 1962). Corticosteroids rapidly became the treatment of choice, splenectomy being reserved for refractory cases. Dameshek and Schwartz (1960) reported the use of purine antagonists in the management of autoimmune haemolytic anaemia, and this has now been accepted as an additional treatment. It has been suggested that primary thrombocytopenic purpura and acquired haemolytic anaemia might have a common aetiology (Evans *et al.*, 1951), since thrombocytopenia may be a feature of autoimmune haemolytic anaemia, and in a proportion of cases platelet antibodies can be demonstrated.

In the following case a relapse of thrombocytopenic purpura occurred in a patient with autoimmune haemolytic anaemia who had previously been treated by corticosteroids and splenectomy. High doses of corticotrophin temporarily controlled the thrombocytopenia, which later was successfully treated with mercaptopurine.

CASE REPORT

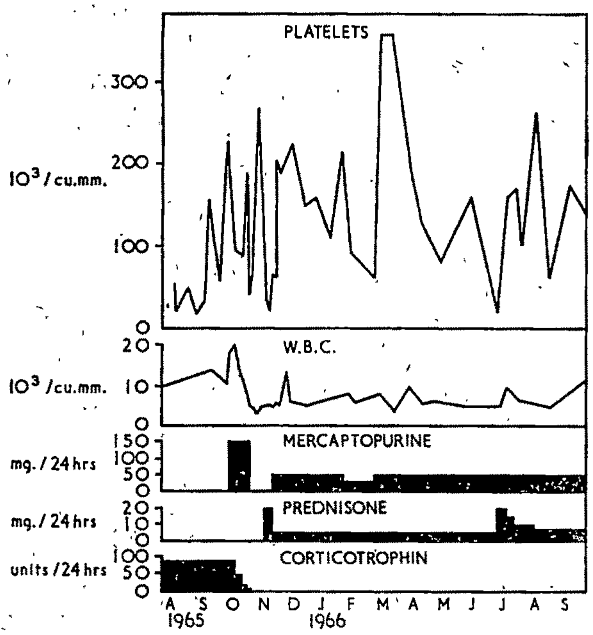
A 17-year-old youth was admitted to hospital in January 1962 with a three-months history of increasing weakness and lassitude. Immediately before admission he developed high fever, became jaundiced, and started passing dark urine. There was no relevant past or family history, and no history of blood transfusion or exposure to drugs or poisons.

Physical examination showed a febrile, pale, jaundiced youth with slight hepatosplenomegaly. Investigations showed haemoglobin 3.5 g./100 ml.; reticulocytes 31%; W.B.C. 22,800/cu. mm., normal differential; platelets 48,000/cu. mm.; serum bilirubin 5.2 mg./100 ml. (1.5 mg. direct). A direct Coombs test was positive. Autoimmune haemolytic anaemia was diagnosed and treatment with prednisone was started, and within four weeks the peripheral blood picture had returned to normal. On a maintenance dose of prednisone 10 mg./day he remained well, with a normal haemoglobin and platelet count, until early in 1964, when he developed a diffuse petechial rash. Platelets numbered 24,000/cu. mm., and after increased doses of prednisone (20 mg./day) had failed to control the thrombocytopenia splenectomy was performed in March 1964. The platelet count did not rise greatly after operation, and prednisone 10 mg./day was restarted with considerable improvement. On this dose of prednisone for the next year the platelet count remained between 100,000 and 200,000/cu. mm.

In July 1965 he was readmitted to hospital with a recurrence of purpura and a platelet count of 20,000/cu. mm. A corticotrophin infusion produced a satisfactory rise in platelet count to 200,000/cu. mm., and this was maintained as long as the dosage of corticotrophin was not dropped below 80 i.u./day. During a two-months course of corticotrophin administration the patient gained 35 lb. (15.9 kg.) and developed many features of Cushing's syndrome.

In October he was admitted to hospital for a trial of mercaptopurine. On examination he presented the appearance of Cushing's syndrome, with moonface, buffalo hump, high colour, and abdominal striae. Blood pressure was 160/120. The initial peripheral blood picture was: Hb 14.9 g./100 ml.; W.B.C. 11,800/cu. mm., normal differential; platelet count 230,000/cu. mm.; E.S.R. 3 mm. in first hour; blood was also examined for lupus erythematosus cells with negative results. A direct Coombs test was positive in a dilution of 1/16, but serological study failed to reveal platelet or leucocyte agglutinins or incomplete platelet antibodies, and the red cell antibody showed no specificity. Apart from a serum potassium of 2.7 mEq/l. on admission, later corrected by oral potassium supplements, other electrolytes were all normal. The urine contained a trace of sugar. Blood-volume studies showed a normal red cell mass and plasma volume, and $T\frac{1}{2}$ ^{51}Cr red cell survival was 27.5 days.

At the time of admission on 4 October he was receiving corticotrophin 40 i.u. b.d. On the following day treatment with mercaptopurine 150 mg. o.d. was started, and during the next three weeks the corticotrophin was gradually reduced, finally being stopped on 24 October. Meanwhile the patient noticed transient symptoms of dizziness and lassitude. At the same time the urine became free of sugar, the blood pressure settled to normal, and he lost 14 lb. (6.4 kg.) in weight. During a 23-days course of treatment with mercaptopurine the platelet count ranged between 40,000 and 180,000/cu. mm., and the white cell count fell steadily from 21,000 soon after admission to 3,200 (see Chart).



Effect of treatment on platelet and white cell count.

The patient was discharged without purpura on 8 November, with a platelet count of 270,000/cu. mm. He was not receiving treatment. Five days later, having developed diffuse purpura, he was readmitted to hospital with a platelet count of 33,000/cu. mm. Prednisone 20 mg./day was started immediately, but when, on 19 November, a platelet count was only 62,000/cu. mm. mercaptopurine was reintroduced at a dosage of 50 mg./day and the prednisone cut to 5 mg./day. Three days later a platelet count was 204,000/cu. mm., and during the next two and a half months on this drug regimen it remained between 100,000 and 200,000/cu. mm.

On 1 February 1966 the dosage of mercaptopurine was halved to 25 mg./day, and this was followed on 1 March by a recurrence of purpura (platelets 58,000/cu. mm.). Mercaptopurine was increased to 50 mg./day, and a week later there was no new purpura and the platelets were 360,000/cu. mm. On this regimen of treatment the patient remained well until 3 July, when he developed purpura. When seen at the hospital two days later a platelet count was 18,000/cu. mm., W.B.C. 5,600/cu. mm., and Hb 16 g./100 ml. No cause for the relapse of purpura was established, and the dosage of prednisone was increased to 20 mg./day. Eight days later there was no sign of purpura, a platelet count was 186,000/cu. mm. and W.B.C. 10,800/cu. mm. Since then the dosage of prednisone has been gradually reduced, and at the time of writing the patient was very well, had no leucopenia, and was able to work as a clerk. On several occasions during the last few months when the prednisone was omitted for a few days he has complained of feeling unwell, but this always cleared as soon as the prednisone was restarted.

DISCUSSION

The occurrence of autoimmune haemolytic anaemia and thrombocytopenia has been recognized for many years (Evans and Duane, 1949). The frequency of their association is not known, but in a series of 83 cases of autoimmune haemolytic anaemia (warm antibody) reported by Dausset and Colombani (1959) 13.2% had a concurrent thrombocytopenia.

In addition to corticosteroids antimetabolite drugs have recently been reputed to be beneficial in the treatment of haemolytic anaemia and thrombocytopenia. Richmond *et al.* (1963) reported a case in which a fulminating haemolytic anaemia and thrombocytopenia developed some time after splenectomy for idiopathic thrombocytopenia. Large doses of corticosteroids were ineffective and thymic irradiation produced only transitory improvement. The thrombocytopenia and anaemia were finally controlled by Imuran (azathioprine) and actinomycin C. Matthews (1965) reported the successful use of Imuran in the treatment of a patient with idiopathic autoimmune haemolytic anaemia and idiopathic thrombocytopenia associated with diffuse hypergammaglobulinaemia, amyloidosis, hypoalbuminaemia, and plasmacytosis. Bouroncle and Doan (1966) reported seven cases of refractory idiopathic thrombocytopenic purpura treated with Imuran. In four of their cases several months' treatment with prednisone and Imuran led to a remission of thrombocytopenia, which was sustained when the drugs were stopped. In two of their cases a definite improvement in platelet count accompanied continuous treatment with the same drugs.

In this case thrombocytopenia developed two years after the appearance of an autoimmune haemolytic anaemia, which was then in remission. Prednisone successfully controlled the thrombocytopenia after splenectomy had failed. A further two years later thrombocytopenia relapsed. Large doses of corticotrophin produced a temporary remission, but in view of the rapid development of signs of corticosteroid overdosage alternative treatment was essential. A trial of mercaptopurine proved successful, and the patient remained well on a maintenance dosage of mercaptopurine and prednisone. This case supports the finding of Bouroncle and Doan (1966) that corticosteroids seem to have an additive effect with antimetabolites in obtaining remission of thrombocytopenia.

My thanks are due to Professor T. A. J. Prankerd and Dr. R. N. Tattersall for permission to publish this case; and to Dr. A. J. Bowdler, who performed the plasma volume and red cell survival studies.

Current Practice

TODAY'S DRUGS

With the help of expert contributors we publish below notes on a selection of drugs in current use.

Radioiodine Therapy of Thyrotoxicosis

Isotopes of iodine are used principally in the investigation of thyroid function, and the chief therapeutic application of radioiodine (^{131}I) is in the treatment of thyrotoxicosis.

Radiobiological Effects

The body does not distinguish the radioisotopes of iodine from stable iodine (^{127}I), and consequently radioiodine enters the circulating iodide pool. This pool normally consists of stable iodide derived from the diet and from the breakdown of the thyroid hormones. Radioiodine is taken up from the iodide pool by the thyroid and is incorporated into the structure of the thyroid hormones. These are released into the circulation and are transported to the tissues. After the breakdown of the hormones the radioiodine, like the stable iodine, may be taken up by the thyroid again and recycled.

The radiation dose from an isotope depends partly on the physical half-life; for ^{131}I this is eight days. Within the body, however, biological factors are also important. The proportion of the dose taken up by the thyroid, the rate of elimination of the radioiodine from the body, and the mass of the thyroid all influence the dose of radiation absorbed from a given quantity of radioiodine. These variables can be estimated and together they determine the effective biological half-life of the radioiodine.

The effects of radioiodine are immediate death of a proportion of the thyroid cells and impairment of secretion and, subsequently, failure of the surviving cells to divide. Furthermore, the ability of the cell to divide is related to the dose of radioiodine. These effects have been shown in laboratory animals[1 2] and can be deduced from observations in man.[3 4]

Dosage

Radioiodine is usually dispensed in a carrier solution of sodium iodide and is tasteless. The dose is taken by mouth.

There is no uniform method for calculating the ^{131}I dose. Most centres aim to give a fixed radiation dose to the thyroid and this is estimated from the 24- or 48-hour uptake of a tracer dose of ^{131}I and the mass of the thyroid. The latter is usually assessed by palpation but is often inaccurate. The mean estimate of a group of observers will be more accurate than a single observation, and experience in estimating preoperative thyroid weights will help to improve an individual doctor's estimates.[5] Alternatively it is possible to calculate the mass of the thyroid from a thyroid scintiscan.[6] Some therapists still prescribe arbitrary doses based on their clinical assessment of the patient without reference to the thyroid size.

Clinical Effect

The response to radioiodine is not immediate. At least six weeks elapse before any definite improvement is observed, and clinical progress thereafter is variable. The experience of most centres is that about 20 to 30% of patients are still thyrotoxic at the end of a year.[7]

If the patient becomes euthyroid there is the problem of post-^{131}I hypothyroidism occurring later. At first it was thought that hypothyroidism would appear in the first 12 months and that the chance of hypothyroidism developing after then was remote. Long-term follow-up studies of patients treated with radioiodine, however, have revealed an unexpected picture. The incidence of hypothyroidism rises steadily and in 10 years reaches 40 to 50% of all patients treated.[4 8-11] Furthermore, even after this interval there is no evidence of a plateau in the incidence of hypothyroidism.

The presentation of hypothyroidism is frequently insidious and patients who fail to attend a clinic for follow-up are more likely to be hypothyroid; in fact, they probably default owing to the inertia so characteristic of their defective thyroid function. Thus, an incomplete follow-up of patients may grossly underestimate the true incidence of hypothyroidism.

The delay in the control of thyrotoxicosis and the rising incidence of hypothyroidism after radioiodine have led to a reappraisal of the methods of treatment. Many suggestions for improvements in current techniques have been made. Some have little factual evidence to support them. It has been stated that an uneven distribution of ^{131}I in the thyroid is partly responsible for the subsequent hypothyroidism,[12] and prior antithyroid medication has been claimed to produce a more uniform distribution. In a few centres fractionation of the dose is favoured; repeated small doses are given over a few weeks. More recently transient suppression of function in one lobe by external irradiation before radioiodine therapy has been proposed.[13] It is argued that the irradiated lobe will thus survive the ^{131}I-irradiation because uptake of the isotope will be temporarily suppressed. This technique poses additional problems of dosage, and the same criticism can be made of more involved methods of calculating the ^{131}I dose.[14]

Many authorities advocate repeated doses of radioiodine with rapid control of the thyrotoxicosis and acceptance of a high incidence of hypothyroidism. Where regular follow-up is not practicable large doses of radioiodine have been proposed followed by the immediate institution of full replacement doses of thyroxine, thus anticipating the almost inevitable hypothyroidism. With this approach one loses all opportunity of studying the problem further, but in some areas social and economic factors prevail and make this the best compromise. If the patients are not to suffer steps must be taken to ensure that the thyroxine will be taken regularly. There is no published evidence of the reliability of patients in this clinical situation, but experience in other circumstances is not reassuring.

More recently clinical evidence has been published showing that lower ^{131}I doses produce less hypothyroidism.[5] Experimental evidence already existed showing that the radiation dose to the thyroid was the major factor in determining the number of thyroid cells which survived.[1 3] A clinical trial of different doses of radioiodine with over 500 patients has shown a markedly lower incidence of hypothyroidism in a five-year period when smaller doses of ^{131}I were used.[5] Three years after treatment the proportion of euthyroid patients was the same as in the group treated with the higher dose. This study employed a single dose of radioiodine, and persisting thyrotoxic symptoms were promptly controlled with antithyroid drugs. This medication was eventually discontinued when the patient had been maintained on a low dose for some time and further treatment appeared unnecessary. The use of antithyroid drugs after lower doses of radioiodine offers a satisfactory programme of treatment for thyrotoxicosis. The delay in the control of symptoms is overcome and the use of lower doses of radioiodine greatly reduces the incidence of hypothyroidism.

Selection of Patients

Radioiodine therapy has usually been restricted to patients over 40 years of age. This decision arose from uncertainty about the side-effects of ^{131}I therapy, and particularly the effects upon the gonads. Apart from this restriction ^{131}I therapy is suitable for all patients. The advantages of radioiodine therapy are the ease of administration, which can be arranged on an outpatient basis, and the rarity of recurrence of thyrotoxicosis. Compared with thyroid surgery there is no risk to the recurrent laryngeal nerves, tetany never supervenes, and the general hazards of majory surgery are avoided. This aspect is especially important in older patients. Careful follow-up of patients after thyroid surgery reveals an incidence of hypothyroidism varying from 5% to 25%, and there is a definite risk of recurrence. Antithyroid medication alone will control the patient's symptoms, but the relapse after a prolonged course of tablets is 60–80% in patients over 40 years of age.

Side-effects

Theoretically radiation from ^{131}I might induce leukaemia or thyroid cancer, but the available evidence does not support either possibility in adults. The incidence of leukaemia is the same in those patients who have had radioiodine therapy as in a population of the same age and sex distribution.[15, 16] Likewise, neoplasms do not appear to be induced in adults, although in children ^{131}I therapy has resulted in thyroid cancers.[17] When antithyroid drugs are used after radioiodine therapy the dosage should be reduced to control the symptoms without producing hypothyroidism. There is experimental evidence in rats that high doses of antithyroid drugs after ^{131}I therapy can produce neoplastic changes in the thyroid.[18] Presumably the excessive stimulation by thyroid-stimulating hormone, which occurs in hypothyroidism, is partially responsible for these changes in the irradiated thyroid cells. Thyrotoxic crises after radioiodine have been described but are rare. Early transient hypothyroidism is an uncommon feature—in contrast to the late-onset hypothyroidism which is permanent. It has been suggested that an autoimmune reaction in the thyroid might be initiated by the irradiation. Although there is a slight rise in the antibody titres it is not sustained and there is no evidence that this mechanism is related to the post-^{131}I hypothyroidism.[19] Effects on other iodide-concentrating tissues have not been described, but the relatively low uptakes are unlikely to result in any significant radiation.

Conclusion

Radioiodine therapy offers a convenient and effective form of treatment for thyrotoxicosis. Experience has shown the two main disadvantages to be delay in the control of thyrotoxicosis and a rising incidence of hypothyroidism. Other side-effects are very rare. Experimental studies have led to a better understanding of the effects of radioiodine on the thyroid cell. These observations, coupled with long-term reviews of patients treated with radioiodine, have offered both an explanation and a possible solution to the problem of hypothyroidism after ^{131}I therapy. Lower doses of radioiodine will reduce the incidence of hypothyroidism. At the same time the proportion of euthyroid patients after a few years is not diminished and recurrence of thyrotoxicosis has not proved to be a problem. Lower doses of radioiodine delay control of hyperthyroidism, but the use of antithyroid drugs to suppress symptoms until the radioiodine has been effective is a rational approach and one which avoids repeated doses of radioiodine. Further clinical trials will reveal the optimum dose of radioiodine, which may well be lower than those already studied.

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Familial Tendency in Cancer

Q.—*What is the evidence, if any, that a tendency to cancer is familial?*

A.—Cancer is not a single disease but a group of many different diseases with some features in common.

There is a strong familial tendency in the susceptibility to a few, mainly rare, types of cancer—e.g., cancer of the colon and rectum associated with familial polyposis, cancer of the central and peripheral nervous system associated with von Recklinghausen's neurofibromatosis multiplex, and a number of other rare hereditary syndromes, and cancer of the skin associated with xeroderma pigmentosum. In the case of most of the commoner types of human cancer, however, a familial tendency, if it exists at all, is very weak. In this connexion particular attention has been directed towards cancer of the breast.[1]

It is perhaps interesting to consider the question also from a theoretical point of view. Studies on laboratory animals strongly suggest that genetic factors affect both the spontaneous incidence of cancers of particular types and the ease with which they can be deliberately induced by exposure to carcinogenic agents. Multiple genes tend to be involved in the case of each type of cancer. Such differences in susceptibility may be greatly magnified by intensive inbreeding (e.g., brother–sister mating for several generations).

Different races of man differ considerably in mortality from specific types of cancer, but many of these differences appear to be determined by environmental rather than genetic factors. Between individuals of any one race, provided that there is no inbreeding, genetically determined differences are unlikely to be obvious because of the multiplicity of genes involved and the kaleidoscopic-like heterogeneity of individuals.

Studies on experimental animals also tell us that it is possible to confuse the effects of vertically transmitted cancer viruses (i.e., cancer viruses passed from parent to offspring) with those genes. At present there is no known example either of a human cancer virus or of the vertical-transmission of such.

For the most part, therefore, cancer patients and their families may be told unequivocally that there is no reason to fear that a heightened susceptibility to cancer of the same or other type has been, or will be, transmitted to the next generation. Only in relation to certain rare types of the disease is this liable to happen.

Virus Infections and Foetal Malformations

Q.—*Can virus infections, other than rubella, in the first trimester of pregnancy cause foetal malformations, in particular spina bifida? If no relationship exists what is the likelihood that a second child may have a spina bifida or a similar congenital deformity?*

A.—There is no good evidence that any virus infection, including rubella, can cause spina bifida. The recurrence risk of a neural tube malformation in children born after one child with spina bifida is of the order of 4%,[1] though the risk may be a bit higher in the areas where incidence of neural tube malformations is high.

Pre-oxygenation

Q.—*I believe there is a method of dental anaesthesia in which oxygen is administered initially followed by N_2O alone. Is this satisfactory and can it be used with a Boyle machine?*

A.—The technique of "pre-oxygenation" to which the questioner refers is that described by Mostert[1] as a development of the original work of Neff, Mayer, and Thompson.[2]

Provided that alveolar distribution is not grossly uneven, the inhalation of pure oxygen for two minutes results in the "washing-out" of 98% of the nitrogen in the lungs and a rise in the oxygen gradient across the pulmonary epithelium from about 60 mm. Hg to some 600 mm. Hg. In the average adult some 1,800 ml. of oxygen can then be eliminated or absorbed from the lungs before the oxygen tension in the alveoli falls to the normal level of 100 mm. Hg.

In practice the inhalation of pure oxygen for two minutes is followed by the substitution of pure nitrous oxide for one minute, and this is generally adequate for the production of anaesthesia in the healthy without apparent impairment of the patient's oxygenation. After this oxygen is added to the inspired gas to form at least 20% of the mixture, together with any supplementary agent thought desirable if the surgical procedure is expected to last more than two to three minutes. Subject to this limitation of time available for surgery, the technique is said to be satisfactory for dental and casualty work once proficiency in its use has been acquired.

The technique does not require a flow greater than 10 litres per minute of either of the gases. A Boyle's machine can therefore be used. It should be noted, however, that the two narrow-bore tubes often used to connect an intermittent-flow machine to a nasal mask for dental work are not suitable for use with Boyle's machine. In these circumstances such tubes may impose a high resistance to free inhalation from a reservoir bag, in which the gas pressure is normally only slightly above atmospheric.

Gaucher's Disease and Pregnancy

Q.—*Does pregnancy occur in women with Gaucher's disease, and how does it affect the condition? What is the risk of the child being affected?*

A.—Gaucher's disease is a metabolic disorder in which the cerebroside kerasin is deposited in the reticuloendothelial system. It occurs as an acute or infantile type and as a chronic or adult type. It affects both sexes and is said to be slightly more common in females.

Women with Gaucher's disease are normally fertile,[1] and when pregnant a normal prenatal course is to be expected. There is no higher incidence of abortion than in the normal population and no undue haemorrhagic complications occur. Gaucher's disease is not an indication for therapeutic abortion, since there is no evidence that pregnancy has a deleterious effect on its course. There is one report of a patient[2] with the disease in whom delivery by caesarean section was required on three occasions because of disproportion due to the involvement of the pelvic bones with Gaucher's infiltration.

The disease may be inherited in three distinct ways.[3 4] In a few families the adult form is transmitted as an autosomal dominant. It would be expected that 50% of the children would therefore be affected. Secondly, and by far the most common, is the inheritance of the adult form as an autosomal recessive. It would be expected that 25% of the children would be affected, but from family studies the incidence would seem to be less than this. Finally, there is a small group in which neurological involvement is associated with an acute illness and poor prognosis. Again this is thought to be inherited as an autosomal recessive.

Inverted Vision

Q.—*What might be the cause in an apparently normal girl aged 8 of fleeting attacks of inverted vision?*

A.—The most likely explanation for this most unusual symptom is the aura of migraine, in which, in addition to objects appearing too large (macropsia) or too small (micropsia), there are many other types of distorted vision—for example, objects appearing more distant (teleopsia).

It would be interesting to know whether the attacks are followed by headache or whether there is migraine in the family. Disturbances of this sort are also seen as an aura of temporal lobe epilepsy, and for this reason the results of electroencephalography would also be interesting.

Pink Staining on Napkins

Q.—*What is the cause of pink staining that appears on napkins on washing and disappears when the washed napkin dries on the line?*

A.—Pink staining appearing on napkins is due to bile pigments. They usually give a green colour, but may cause a pink stain temporarily. A pink colour that turns brown is due to the very rare condition of alcaptonuria and is caused by the excretion of homogentisic acid in the urine.

Notes and Comments

Cold Water for Burns.—Dr. A. WARD GARDNER (Fawley, Hants) and Dr. P. J. ROYLANCE (Kingswood, Surrey) write: We would disagree with your expert ("Any Questions?" 3 June, p. 623) when he states that "immediate application of cold water cannot at present be recommended as a first-aid treatment, except possibly for small burns." Burns and scalds first cause pain and tissue damage, then loss of blood plasma into the tissues surrounding damaged capillaries. The aims of the first-aid treatment of burns are to prevent further damage, to prevent infection, to minimize the effects of loss of fluid from the burned tissues, to reassure the burned person, and to transport the casualty swiftly to hospital.[1]

The work of Ofeigsson[2 3 4] and others[5 6 7] has demonstrated beyond reasonable doubt that immediate cooling not only arrests further thermal injury but minimizes the resultant loss of tissue and skin damage from a heat burn or scald. If clean, cool water is to hand showering or immersion relieves pain drastically and takes less time than producing sterile dressings of the right size and sterility.[8] Ten minutes spent cooling a burn will not significantly affect the hospital treatment of a burn, but it may greatly affect the amount and depth of local thermal injury. Bloch[9 10 11] clearly shows that local cooling is an effective and readily available first-aid procedure, which in fact has been extensively used in the U.S.A., and may be the only means of providing first-aid treatment in the care of casualties.

Book Reviews

Modern Forensic Medicine

Modern Trends in Forensic Medicine—2. Edited by Keith Simpson, M.A.(Oxon.), M.D.(Path.), F.R.C.P.(Lond.), F.C.Path., D.M.J. (Pp. 374+x; illustrated. £4 18s.) London: Butterworth. 1967.

This book is not described as a second edition but as a second series, and this is surely true, since its 13 chapters are entirely different from the 12 which appeared in 1953. The subjects dealt with are of equal importance, and these two books together constitute a comprehensive account of recent developments and modern views in forensic medicine. Professor Simpson is himself responsible for two of the chapters. One is on the pattern of traffic accidents, a rather neglected subject in this country, and his study may advance safety designs and precautions in motor vehicles. In his other chapter Professor Simpson deals with the cardiomyopathies, underlining the fact that these diseases, once thought to be extreme rarities, may be responsible for many unexplained deaths.

Professor Simpson has cast his net widely in his selection of authors of the other chapters but has yet kept it within the British Isles, and has managed to persuade the most eminent scientists to contribute to this valuable book. Perhaps one of the most valuable chapters is that by Dr. Keith Mant on the estimation of time of death, which he acknowledges to be still one of the most controversial problems in forensic medicine. Dr. Mant's review of the present situation in this field gives one hope that this estimation will shortly move from the field of intelligent guesswork to that of scientific exactitude.

It is invidious to mention the names of authors of individual chapters without praising all of them, but naturally any individual reviewer is likely to find his interest taken by one chapter more than another, and it is only in this sense that I would mention the value of Dr. Goulding's chapter on side-effects of drugs and of the chapters on forensic immunology by Dr. Pereira and blood-group systems by Dr. Grant. All these three chapters deal with modern problems in an up-to-date manner and are of extreme value to the practising forensic expert.

The present volume appears in a different size and shape from No. 1, and this standard size is certainly more convenient for most library shelves. One must expect to pay 98s. for such an authoritative volume as this nowadays, but the price probably puts it out of the range of undergraduate students of forensic medicine. On the other hand, it must be considered an essential in the library of every practising forensic scientist.

R. DONALD TEARE.

Military Medicine

Radiology in World War II. Edited by Kenneth D. A. Allen, M.D. (Pp. 1087+xliii; illustrated. $8.25.) Washington: Office of the Surgeon General, Department of the Army. 1966.

This is the thirty-second volume published in the history of the U.S. Army Medical Department in World War II. In this huge tome written entirely by radiologists who served in the war, an honest attempt is made to record events so accurately, fully, and candidly that the many radiological errors made during that war will not be repeated in future.

Throughout the book we meet the recurring demand for the appointment of radiological consultants of standing with the Surgeon General and at all operational headquarters, for the placing in hospitals of chiefs of the radiological service, independent of the physicians and surgeons and responsible to the commanding officer only, and for the grading of radiographic technicians on a level at least equal to that allotted to their dental and laboratory counterparts. It is emphasized that the radiologist should always be a better radiographer than his technicians.

The training schedules for turning multitudes of ordinary doctors—mainly paediatricians—into radiologists and enlisted men into technicians were quickly brought into operation. The early "de Lorimier's 8-week wonders" gave place eventually to 12-week graduates at the hands of that brilliant organizer and teacher of radiology.

The story of each campaign and field of operations, from frozen Alaska to sweltering New Guinea, from Normandy to Okinawa, is told in separate chapters, each with operational, mechanical, and minute clinical detail, so there is a good deal of inevitable repetition.

The absence of standard apparatus with interchangeable parts (44 models made by 33 makers), the insufficient tropicalization with resulting deterioration, corrosion, and loss of insulation, and the high rate of cable failure when sets were required to operate therapeutically at voltages never intended by the makers resulted in many difficulties. Sheet lead was always in short supply.

The writers express the opinion that for success morale was always more important than hardware, and one reads with admiration how apparently insurmountable difficulties from moulds, damp, lack of water, and unventilated developing tents were overcome. "Improvisation and scrounging were the order of the day."

The general standard attained on all fronts was high. Myelography, pneumoarthrography, and cholecystography were carried out in the most remote places. The extent to which therapeutic radiology was employed on active service is astonishing, in Europe for plantar warts and clostridial myositis, in the East for jungle sores, fungous infections of the skin, for eczematoid dermatitis, and for cutaneous leishmaniasis.

Excellent relations with the British are reported from all fields and high praise is given to Brigadier D. B. McGrigor and to the staff of the R.A.M.C. College for generous aid afforded. Praise is recorded for help given by native practitioners trained at the Suva Medical School in Fiji.

At the outbreak of the war the cyclotron workers at Berkeley, California, and the staffs of cancer radiotherapy units were among the few persons in the United States who were accustomed to dealing with dangerous radiation.

The appointment of Professor Stafford L. Warren to advise on protection aspects of the "Manhattan Engineer Project" with the pioneering duty of determining and combating the radiation dangers of producing U 235 and plutonium in atomic piles and of disposing of waste and effluents, plus coping with the many medical and psychological problems resulting from isolating a million people in three secret cities, was an outstanding success. The full story of the project is told by Colonel Warren himself with operational and clinical details of the drops on Hiroshima and Nagasaki and of Operation Crossways at Bikini Atoll, where the capacity and deadly aspects of the Bomb were investigated and analysed after the surrender of the Japanese. A new world era started at Alamogordo, New Mexico, on the sixteenth of July 1945.

This big volume is full of interest from start to finish and its editor, Professor K. D. A. Allen, it to be congratulated.

GEORGE R. MCROBERT.

Teaching Human Reproduction

Teaching the Biological and Medical Aspects of Reproduction to Medical Students. Report of a Macy Conference, New York. (Pp. 151+xiii. 44s.) New York and London: Harper & Row. 1966.

In 1955 the Josiah Macy Jr. Foundation set itself to "strengthen the establishment of human reproduction as the basic science of obstetrics, through support of education and research in this field." This book is the report of a conference, held in Princeton, New Jersey, in 1965, to discuss some of the more promising developments in teaching human reproduction.

There has undoubtedly been a serious reappraisal of medical education in recent years, and no department has been under closer scrutiny than that of obstetrics and gynaecology. In training physicians who will practise in a sophisticated, largely urban society we are gradually moving away from the apprenticeship system of acquiring manual skills to an intellectual process of education in reproductive biology. Further, it is accepted that the study of human biology is an important component of a liberal education, that the educated members of society look for a lead in this, and that the physician should be able to provide such guidance. The urgent need for such study has come largely from the world population problem and from recent developments in the field of birth control; but, setting these aside, there is need for a fundamental reorientation of medical education in the direction of positive health, away from the preoccupation with morbid processes, which was essential half a century ago.

In this country we have scarcely begun to think in these terms ourselves, let alone change our syllabus, examination requirements, or teaching methods to take account of this present need. It is therefore of great interest to read of the practical experience of American medical schools with programmes integrating the teaching of departments of anatomy, physiology, pharmacology, psychiatry, and obstetrics. In some centres separate courses in reproductive biology have been instituted, in others the departments of obstetrics have altered their course to place greater emphasis on such topics as the morphological and physiological aspects of spermatogenesis, ovulation, fertilization, the endocrine control of these processes, human genetics, the social and physiological aspects of sex, biostatistics, and population control. Current ideas about the psychology of learning are also illustrated by application. A section of the conference was devoted to the study of methods of teaching reproductive biology outside America. British experience was presented by Sir Dugald Baird, and contributions were made by representatives from Germany and Japan. In both the latter the teaching appeared to have been influenced little by modern thought.

The editing of the papers has been good so far as the main contributors are concerned, but too little of the discussion is presented and one never obtains an impression of the way in which the papers were received. However, brevity in this case has paid some dividends, for the ideas of the contributors are lucidly presented. In all, this is a stimulating book of interest to all teachers of medicine, whether academic, scientific, or clinical.

R. W. Taylor.

Exotic Dermatology

Color Atlas of Dermatology. By Joseph Kimmig, M.D., and Michael Jänner, M.D. (Pp. 304+ix; illustrated. £15 15s.) Philadelphia and London: W. B. Saunders. 1966.

This is the third edition of a well-known *Color Atlas of Dermatology* originally assembled by Friebos and Schönfeld but now completely redesigned and enlarged by Kimmig and Jänner with many new illustrations. The text is also rewritten and in the English and American publication this has been amended by Dr. Goldsmidt.

This is a superb book. The coloured illustrations are truly magnificent and include common, rare, and exotic conditions. It will be of great value to many people. The senior dermatologist may well pick out an unusual condition rarely seen or recognized, and will refresh his memory of eruptions he does not see frequently at the present time. In this respect the collection of syphilitic eruptions is particularly useful. Junior dermatologists and postgraduate students will find this book of great help, as they will see unforgettable pictures of some conditions which they may have missed during their training. Students, preregistration house-officers, and general practitioners could well spend a few hours looking through the atlas and will then appreciate the appearance of some of the conditions they have heard of but not seen. For those dermatologists who have not built up a collection of coloured slides for teaching there is invaluable material available.

Criticism can be made, but only over minor matters. With ringworm fungus infections the dermatologist is now thinking in terms of the actual infecting fungus and the generic term of *Tinea* is not a sufficient diagnostic label. A few photographs are not up to standard and could easily be improved in further editions. The scabies illustration is very poor and the types of cavernous haemangiomata are badly represented. There are also bound to be some omissions and, for example, there is no photograph of orf (contagious pustular dermatitis of sheep).

The book is apparently expensive (£15 15s.), but when consideration is given to the excellent production of over 900 coloured photographs this is not a high price, and it is a book which should be in every large dermatology department, particularly where there is postgraduate training.

R. P. Warin.

Dynamic Psychiatry and the G.P.

Absent. School Refusal as an Expression of Disturbed Family Relationships. By Max B. Clyne, M.D. (Pp. 269+xi. 38s.) London: Tavistock. 1966.

Here is a remarkable example of the work that general practitioners can do when awakened to the potential that exists in their daily work. At the present time Michael Balint may take full credit for this awakening. It is indeed astounding that a general practitioner, while keeping at work, can make this kind of clinical study, dig deeply and wisely into the vast literature, and then find the emotional drive that is needed for the writing up of the data, the ideas, and the theoretical possibilities and suggestions.

Dr. Clyne has taken this one theme, school refusal, neatly and properly dissected out from truancy, and has allowed himself, as was necessary, to look at life through school-refusal-coloured spectacles. In the end he makes a comparative study of theories and then offers a theoretical formulation. The reviewer would like to find this formulation good, because it is based on his own formulation (fully acknowledged) of "transitional objects and phenomena," an area of the mind between subjectivity and the acceptance of the reality principle; but there is no need to jump to final conclusions, for Dr. Clyne proffers his idea with appropriate modesty.

"I have discussed the various aetiological theories of school refusal as described in the literature. I thought that these theories (environmental, sociological, neurasthenia, phobia, separation anxiety, test anxiety, depression, crisis) were insufficient to explain all the features of school refusal. I have put forward a relationship hypothesis according to which school refusal is based on a disturbance of the child's relationship function leading to a regression to the infantile, transitional stage in the development of object relations."

In Chapter 8, of which this has a summary, he has made his meaning clear to anyone who can give some time and thought to what is written, and to the work on which it is based. The main thesis is that it is for the general practitioner to work on these cases, keeping his mind open for all kinds of aetiological factors, and not passing on each case to specialists unless of course he is not temperamentally fitted for the kind of investigation that is needed in each case.

Much that is dealt with in passing should be noted. For instance, the matter of the physical examination, "discovered in the eighteenth century," and now (one would think) in danger of dying out. The patient needs to be physically examined, and perhaps it is the psychoanalyst who knows this best. The theory around all this is interesting and indeed important for medical practitioners.

In the reviewer's opinion the last word has not been said on the theory of school refusal, but this book leads us somewhere nearer to it. It should be read by general practitioners for its side-issues, and as a stimulus to clinical observation, and as an encouragement to those who are in the best position for doing clinical research—provided they are not allergic to dynamic psychiatry and to the idea of unconscious motivation.

D. W. Winnicott.

Proteins and Genetics

Protein Biosynthesis and Problems of Heredity, Development, and Ageing. By Zhores A. Medvedev. Translated by Ann Synge, B.A.(Physiology), M.B., B.Chir. (Camb.). (Pp. 584+xxi; illustrated. £5 10s) Edinburgh and London: Oliver & Boyd. 1966.

It is a pleasure to welcome a Russian textbook translated into English which deals with modern genetics and protein biosynthesis. The Lysenko period is now a memory only, and the translator mentions that the earlier copies still contained detailed and strongly worded attacks on Lysenko, which are now replaced by a more general discussion. Medvedev is not the only Russian author in this field whose publications have recently been published in the West. Spirin is studied regularly, and Dubinin's *Molekulargenetik* (in German) is read widely. Medvedev is a gerontologist and this book contains a particularly interesting chapter on changes in proteins and nucleic acids with age, and on the problem of ageing at the molecular level.

The monograph follows the conventional pattern one expects from a textbook in the field of molecular biology. One part deals with the synthesis of proteins in general, and another with special features such as the reproduction of viruses. Yet others describe the specific reproduction of proteins and nucleic acids, and their biosynthesis. The translation (by Ann Synge) is excellent, and there is no indication that this work was not written in English originally. The book was published in Russian in 1963 and must have been written in 1962. A special supplement for the English edition summarizes in 25 pages some of the important advances made in 1963 and 1964. Even so the book is not quite up to date and some speculations which may have been of interest in 1962 are no longer relevant because the facts have been discovered since.

There are numerous illustrations, some original, some familiar, all of them excellent. Each chapter is followed by references and the reader will find them a help in gaining access to Russian as well as to Western original work. An alphabetical index to all references lists some 2,000 names, and refers to many more publications. A subject index is not provided, but the reader is helped by a very full table of contents. There are now a number of textbooks of this nature available, but those who choose this clear and well-written treatise will not be disappointed.

H. LEHMANN.

Dental Caries

Advances in Fluorine Research and Dental Caries Prevention. Vol. 4. Proceedings of Congress, Utrecht, 1965. Edited by P. M. C. James, Klaus G. König, and Hans R. Held. (Pp. 246+viii; illustrated. £6.) Oxford, London, Edinburgh, New York, Toronto, Paris, and Braunschweig: Pergamon. 1966.

Epidemiological studies into the incidence of dental caries and the clinical testing of agents of use in its prevention are being conducted in many countries, and the publication of the proceedings of the symposium on "The Clinical Testing of Agents for the Prevention of Dental Caries" has come at an opportune time. One of the difficulties in this type of work has been that the results obtained in different countries have often appeared to be in disagreement; and, while this may have been due to variables of which we are, as yet, uninformed, it may on the other hand be the result of differences in techniques of observation and recording which could be more precise.

That workers of international repute with experience of epidemiological studies in dental caries in various countries should have come together in order to discuss these matters, and that the results of their deliberations are made available to us in this book, is certainly to be welcomed. In many countries throughout the world postgraduate diplomas in public dentistry or dental public health are being instituted, and it seems probable that this book will be recommended reading for many of them.

In addition to the report on the symposium there are also nineteen free papers by research workers, many of whom are as distinguished as those participating in the symposium. Many of these papers are of considerable interest and value. The paper, printing, and illustrations are of excellent quality, but, even though this publication has apparently been subsidized by industry to a considerable extent, the price of £6 is somewhat expensive. There may be few individuals who will wish to purchase this work, but it should certainly be included in the library of any university with a dental school.

A. D. HITCHIN.

Queen's Nightman

The Story of William Hunter. By Sir Charles Illingworth. (Pp. 134+viii; illustrated. 35s.) Edinburgh and London: E. & S. Livingstone. 1967.

In the past a student of William Hunter would read the lecture by his contemporary and admirer Samuel Foart Simmons (1783), the later memoir by Peachey (1924) which contains much factual information, and the account by Marshall and Burton in the Glasgow Museum catalogue (1962) and other works. He would find some variation in emphasis and some inevitable contradictions in detail. Sir Charles Illingworth has added to these a comprehensive study of the lives of Hunter's contemporaries, the many bundles of letters in the University of Glasgow and in the Hunter-Baillie collection in London, the periodicals current at the time, and the writings of William Hunter.

It was a happy inspiration of genius to combine all this information into an autobiography as it might have been written by William Hunter himself. Instead of a large collection of facts we are given a continuous narrative of surpassing interest, written in a conversational manner without insistent demand on strict chronological order. Such a style gives a more favourable picture than might have been painted by others but it does not exclude mention of any self-admitted imperfections of character.

The influence of William Cullen, his first mentor in medicine, is apparent throughout the story. Hunter relied on him for the care of his ailing relatives and for advice in his undertakings and he remained "his dear friend." Through Cullen's introduction he met another compatriot, William Smellie, who taught him midwifery and sent him to lectures on anatomy by Frank Nicholls and on natural philosophy by Desaguliers; their different styles influenced his subsequent teaching. In the exuberance of youth he soon thought himself superior to Nicholls and wished to succeed him. James Douglas of the "pouch," a skilled anatomist and an experienced obstetrician, invited him to be his resident assistant, and despite the reluctance of his father who was ill William accepted. Youthful ambition again prevailed and he found no reason to make any sacrifice of his own interests. Douglas played a major part in framing his career.

William determined that the teaching of anatomy must include practical dissection. His rise in obstetrics culminated in his appointment as Queen's Nightman; he learned diplomacy from dealing with the labours of the aristocracy.

William's attitude to his brother John was kind but at first condescending; he was surprised to discover his manual dexterity and inquisitive spirit and his outlook changed to one of pride in his skill and reliance on his help, which he acknowledged generously during the fruitful years of their co-operation. John's tribute to William is not mentioned. The famous quarrel is dismissed briefly with "John was ever hot headed and is now getting more quarrelsome, or so I am told." It is put in its proper perspective in the final scene—"Our little feud is over."

This entrancing story tempts one to assess William's character. His simple tastes were not altered by his rise to fame. He was ambitious, perhaps jealous and a little selfish, but he was compassionate and generous albeit thrifty. Blessed by a good education he became a man of erudition as well as a skilled anatomist and obstetrician.

The thanks of all Hunterians are due to Sir Charles for this most attractive and readable book. The production is excellent but it is worthy of a fuller index. The appendices are useful; reference 169 should be for Chapter 18, not 16.

MEDICAL EDUCATION

Need for Integrated Training Schemes*

P. W. R. M. ALBERTI,† PH.D., M.B., F.R.C.S.

Brit. med. J., 1967, 3, 101–102

It is my aim today to look ahead and see how the National Health Service might evolve to prevent further disillusionment among hospital junior staff. Doctors the world over have been notorious for their lack of forward planning, a lack which is only second to their universal cries of dismay when Governments plan for them. I feel privileged to participate in this break with tradition, in what I believe is to be the start of a constructive attempt by the profession to influence the evolution of the Health Service.

I would like to examine two major grievances of the hospital junior staff and suggest some possible remedies. These are the long and uneven training, and the total uncertainty of a future in the hospital service.

Postgraduate Training

There is growing feeling that postgraduate training, with certain noteworthy exceptions, is frighteningly haphazard: its quality is uneven, its length variable, and its diplomas multitudinous and often misleading.

In view of the increasing shortage of doctors in all branches of the profession the question today must be: "What is the shortest period of training required to fit a man for a consultant post?" If this is accepted, then formal instruction inevitably follows. I believe training programmes in the specialties must come to Britain if we are to continue to produce well-trained consultants for the N.H.S.

The implications of such a change in policy are enormous and would lead to a major reorganization within the hospital sphere. Training schemes must be based on large units or departments, for it is both difficult and uneconomical to provide formal instruction for two or three people, while it is perfectly feasible for 20 to 30. Tuition must be continuous, and practical training well supervised. There are few departments which can undertake formal academic instruction of the postgraduate and at the same time provide facilities for plentiful clinical experience. Some degree of rotation is inevitable. This should be continuous throughout the training period, in and out of the academic unit, revisiting the same hospital at a higher level. Rotation should never imply need for changing residence, for virtually all conurbations large enough to support training programmes have sufficient hospitals close together to allow easy access one to another.

This sort of scheme is possible only if much closer liaison exists between teaching hospitals and regional boards, though it seems difficult under present financing and administrative regulations to adopt a sufficiently flexible attitude to make progress. In my view it is possible to plan on a regional basis only if all parts of the team are working together, and in order to do this the boards of governors and the regional boards might well be combined as they are so successfully in Scotland and Northern Ireland. They must, so far as training is concerned, make regional estimates of needs for hospital staff and plan training posts accordingly.

It will never be possible to establish training for more than a handful of people if it has to be centred on a 30-bedded teaching hospital unit; all that seems to happen is that more and more staff are employed (indeed attracted by the kudos and genuine academic advantage) gaining less and less practical experience, while there may be regional hospitals close by cutting their work loads because of inability to obtain juniors, though they would provide ample experience. The two surely are complementary. The advantage of formal academic training allied to plentiful practical experience would quickly attract juniors.

Regional Centres

What I have said here applies in particular to the specialties: anaesthesia, psychiatry, ophthalmology, otolaryngology, dermatology, and the like, where there is already an incipient staffing crisis, but the same problem will apply to general medicine and surgery in the years to come.

Funds must be put aside for the establishment of one or more regional centres in each specialty large enough to provide the ancillary facilities which are increasingly needed. The Newcastle Region has shown a fine example in some instances, as its neurological, neurosurgical, and radiotherapy services demonstrate, but these are only faint glimmers in an otherwise Stygian gloom. It is the lack of such centres, with their allied training programmes and research facilities, just as much as financial pressures which precipitate emigration among those seeking a future in the hospital service.

The implications of such training schemes are considerable for the Health Service. They would simultaneously provide more consultants and drastically alter the peripheral scene. The most recently available figures of consultant age distribution indicate that it is uncommon for individuals to be appointed to consultant posts before the age of 35. If by swifter and more comprehensive training men were ready at 32 or even 30, the number of consultants would increase by 8 or 13% without any increase in numbers of practising doctors, and would thereby help to eliminate a growing shortage.

A word of warning to juniors is needed at this stage: if they wish this sort of scheme to be introduced, and I believe they do, then they must also realize that it means more and harder work, not more time off and more holidays. One thing is fundamental to training: experience must be gained and there is a limit to spoon-feeding. Any observer of the North American training scheme is immediately impressed by two things: the shorter but more organized training programmes, and the very much longer hours and harder work put in by the residents.

---

* Based on a paper read at the Conference on "The Future of British Medicine" held at Newcastle upon Tyne on 10 and 11 March, organized by the North of England Branch of the B.M.A. (See *B.M.J.*, 18 March, p. 693.)

† First Assistant, E.N.T. Department, University of Newcastle upon Tyne.

If training is to be centred about large institutes, then inevitably there will be no juniors in the periphery. This need not be a bad thing, and in many instances will only stabilize an already current situation.

Some services will be centralized: the large institutes will siphon off patients from the periphery, and as communications improve so the need for small isolated units will diminish. The funds thereby released will help finance the central departments. Hospitals might therefore be built where they can be manned, rather than where political pressure dictates.

Where hospitals survive without training programmes consultants and general practitioners will have to work much closer together. This is one way in which the cry from general practitioners for hospital participation may be answered: they would be employed as integral members of the team in consultant-staffed units, after suitable training. This is quite different from general-practitioner-run cottage hospitals, pleasant though they be, for it enables practitioners to participate in expert first-class units.

Here we must turn to the relations between the Government and the Royal Colleges, and to politics in relation to the social services and the profession. The nation must be persuaded that its funds are better spent in such a hospital structure than they are at present; the Royal Colleges that their examinations and training are most efficiently conducted in defined programmes.

Higher Qualifications

The Fellowship and Membership seem to be inefficient ways of sorting out future consultants. It is my opinion that, by and large, the standard of these examinations is not set too high: if so, it follows that candidates are ill prepared. Much greater note must be taken of the candidates' training before entry. This implies, firstly, sitting later, and, secondly, greater supervision of centres. I think that it is in this latter task that the Colleges can be most faulted. Approved posts for Fellowship and Membership are so variable as to imply a lack of supervision. It is noticeable that nothing so speedily improves the calibre of a training programme in North America as the threat of withdrawal of approval; for once this happens no junior will be recruited. The inspection should be of training programmes, not of posts, and they should be regularly and strictly reviewed. Surgically, I favour the submission of operative experience by candidates, which if small would not jeopardize them, but which if repeatedly small from one unit would jeopardize its programme.

The standard of the further examinations appears to put the cart before the horse. At present the Colleges are reviewing their role in postgraduate training, and, if I read it correctly, the College of Surgeons is suggesting that specialist training be given only after admission to Fellowship, for four years as a senior registrar. The combined pass rate in both parts of the English Fellowship as at present constituted is so low that it is a considerable hurdle in itself. If it is used as an entrance challenge to specialist training in its present form it will both diminish recruitment and unnecessarily lengthen the training period. Genuine confusion also exists at present about the meaning of further diplomas. The Colleges state that they indicate fitness to be trained, but appointment committees assume that they are an indication of training completed and hence of professional competence.

There is obviously a need for some sort of weeding-out examination: it is wrong to think that all those who attempt to specialize are sufficiently able or suitable for training. The selection should be made within three years of qualification, and should carry a fair pass rate. It might take the form in all the specialties of a test in appropriate basic sciences. Thereafter those who continue training should be reasonably certain that after a predetermined period of between two and at the most six years, depending on the specialty, they have a good chance to attain specialist status, possibly with dual standards similar to the Canadian certification and Fellowship, with each major subspecialty having its own examination.

Uncertainty

Already the N.H.S. somewhat grudgingly accepts that senior registrars are career hospital doctors; in the new scheme let it accept this fully. The uncertainty about the most important move in the life of a young hospital doctor, that from senior registrar to consultant, must be unequalled elsewhere in the world, and this fact alone must account for much emigration. Regional boards must know years ahead what posts are to fall vacant by retirement. These could be advertised, and indeed appointed, months or even a year before the candidate finished training and the post fell vacant: this would allow better future planning by doctors and boards alike. The situation would be eased further if retirement was not implemented on reaching the 65th birthday, but at the end of the academic year. At the same time, as in North America, all junior posts could be filled on the same date. A register could be kept of all posts available at the year's end, and, with plenty of warning, juniors and hospitals could plan their future.

CONTEMPORARY THEMES

Memorandum on the Management of Accidents in Childhood*

Prepared by the Standing Committee on Accidents in Childhood of the British Paediatric Association

Brit. med. J., 1967, **3**, 103–105

Children are more liable to accidents than adults because they are immature physically and mentally, lack experience, and are unable to foresee danger and the possible consequences of their actions. Hitherto there has been too little recognition of the facts that children are injured in large numbers, that their injuries differ from those of adults, and that they have special needs related to age and development. The consideration of special provision for children is important now that so much thought, time, and money are being devoted to the planning of hospitals and to the organization of accident and emergency services.

Review of Present Situation

Mortality

Nearly 10% of all accidental deaths in males and 7% of those in females occur in children under the age of 15.† The main causes in the first year are recorded by the Registrar General as inhalation of food, etc., and suffocation, though some of these "cot deaths" may be infective or allergic in origin.

As the toddler begins to explore his environment other causes of death increase in importance: drowning, poisoning, burns and scalds, falls, and traffic accidents. Accidents are the commonest single cause of death among schoolchildren; in 1963 40% (612) of the 1,528 deaths in boys aged between 5 and 15 in England and Wales were due to accidents. The corresponding percentage in girls was 24.7% (224 deaths out of a total of 909).

Morbidity

Rowntree (1950) estimated that about 35,000 injuries in children under 2 years of age were treated annually in the United Kingdom—3,000 by admission to hospital, 11,000 in accident and casualty departments, and 21,000 by family doctors. Children under 15 years of age constituted 22% of patients attending "casualty" departments in England and Wales in one sample week (Platt Committee's Report on Accident and Emergency Services, 1962, Appendix II, Table III).

In Liverpool about 2,000 children (approximately 1% of the childhood population) are admitted to children's hospitals each year as a result of accidents; 1,200 go to surgical wards (over a quarter of all admissions to these wards) and 600 to orthopaedic wards (half of the total admissions to these wards) (Forshall, personal communication).

In 1959 10,907 children and 69,765 adults were seriously injured in road accidents (Interim Report of Accident Services Review Committee, Osmond-Clarke Committee, 1961, Appendix I, Table IV).

Of all poisonings (other than barbiturate), 43% in males occur in boys under 5 years of age, while 53% of all burns in females and 48% of all burns in males occur in children (Hospital In-patient Enquiry for 1959, quoted in Platt Committee's Report on Accident and Emergency Services, 1962, Appendix III, Table III).

A high proportion of accidents involve very young children. According to the British Medical Association's Report on Accidents in the Home (1964), 40% of all home accidents occur in those under 5 years of age: accidents to boys aged 1 and 2 years make up 22% of all reported accidents to males. Of home accidents in Aberdeen, more than half were among children below school-leaving age, though children composed less than one-quarter of the population (MacQueen, 1960).

It should be noted that not all injuries to young children are accidental. Deliberate, serious, and often fatal injury to children by adults seems to be more common than formerly (*Brit. med. J.*, 1966).

Management of Accidents

I. Introduction

Family doctors and casualty officers deal with the majority of minor accidents to children. Serious injuries may be treated by consultant surgeons, while paediatricians are concerned with medical emergencies and acute poisoning. Should an accident cause complicated or multiple injuries many specialists may become involved: the orthopaedic surgeon will deal with the fracture; the plastic surgeon the burn or the dog-bite of the face; and the paediatric or general surgeon the ruptured internal viscera. Thus, though each injury and every complication is expertly dealt with, there may be divided responsibility, fragmentation of care, perhaps overlap of treatment, and failure of total assessment. Because many different specialists are concerned the importance of accidents in childhood, and the size and complexity of the subject, both nationally and locally, may not be sufficiently appreciated. The result will be failure to arouse the public and the professional conscience.

Two general principles should underlie care of the injured child. Firstly his injury should have the best treatment, and secondly his visit to hospital, whether as inpatient or outpatient, should cause him and his parents as little distress as possible. These principles determine the kind of provision that should be made for the hospital care of injured children.

II. Inpatient Arrangements

(a) General Aspects

All children should be admitted to children's units and not to adult wards or to the side-wards of adult units. This important principle is supported by the Accident Services Review Committee (Osmond-Clarke Committee) but is not yet generally accepted, for there are still many children in adult wards. We therefore state our reasons for endorsing it.

Technical.—The emergency resuscitation and treatment of infants and children call for special medical and nursing experience and skills. These include administration of intravenous fluids, collection of blood and other samples for analysis, and understanding of fluid and electrolyte balance in young children. The nursing of infants and young children presents no difficulty in children's wards geared to the daily practice of the specialized techniques used. The best results are obtained by people who are familiar with these methods and with the technical problems presented by emergencies in small children, and who have the right sort of equipment immediately available. These conditions obtain only in large children's hospitals and in large children's units in general hospitals.

---

* Abridged version. Copies of the full memorandum can be obtained from the Secretary, British Paediatric Association, 30 Guilford Street, London W.C.1.

† Throughout this memorandum the word "accident" includes accident, poisoning, and violence.

Psychological.—Children, especially those under 6 years of age, are particularly liable to emotional upset as a result of admission to hospital, and everything possible should be done to minimize this and to promote quick recovery. Only with the special experience and skills mentioned above are the necessary technical procedures likely to be carried out with the minimum of disturbance to the child. The medical, nursing, and auxiliary staffs in a children's unit are expert in dealing with children and acutely aware of their needs, both physical and emotional. Ward routines and arrangements are suited to the needs of children, visiting by parents is encouraged, and mothers can be admitted with their children. Play facilities are available and children have the companionship of others of their own age. Schoolteachers play an important part in preventing the educational handicap which might otherwise develop during a long stay in hospital.

In order to provide the necessary experience and to attract enough doctors and nurses of the right calibre, a children's unit must be large. Spence (1947) thought that the minimum size for a children's unit should be 60 beds, while the Nuffield Foundation report on children in hospital stated that 40 beds should be the minimum, but that where the local population is large enough there should be at least 60 beds (Duncum, 1963).

(*b*) *Inpatient Services in District General Hospitals*

The majority of injured children needing admission to hospital will in the future be treated in children's units in district general hospitals. These units should consist of 60 beds or more and provide for a wide variety of medical and surgical cases. In areas with more than one district general hospital it may prove advisable to concentrate the inpatient facilities in one of them in order to achieve the size necessary for an efficient unit. Obviously it will be more satisfactory if the paediatric unit is in the same hospital as the main accident and emergency department.

In some units, medical, surgical, and orthopaedic cases are nursed together, whereas in others they are in separate wards. Whatever the arrangement, there should be the closest possible liaison between the consultant paediatrician and his surgical colleagues.

(*c*) *Inpatient Services in Regional Paediatric Centres*

There is a definite need for a large paediatric centre in each hospital region to which the more difficult and complex cases can be referred, either directly or by transfer from a district general hospital. The regional paediatric centre should be a children's hospital closely associated with the main regional teaching hospital. The centre should include specialties such as children's orthopaedic surgery, neurosurgery, otolaryngology, ophthalmology, plastic surgery, dermatology, etc., as well as paediatric medicine, surgery, and psychiatry. Such comprehensive provision cannot be effectively made in hospitals of fewer than 200 beds. The services available in the centre would enable a children's accident unit to be established, to serve the surrounding district and to act as the regional reference centre for the more complex problems of accidents to children.

It may be argued that such a children's accident unit should be associated with the adult accident centre rather than with the regional paediatric centre (whether the latter be a children's hospital or a large children's unit in a teaching hospital). A major advantage, however, of associating the regional children's accident unit with the regional paediatric centre is that specialists expert in the paediatric aspects of their subjects will be immediately available. The advantage of having, for example, consultant anaesthetists experienced in the management of small children can scarcely be overestimated, and the same applies to paediatric biochemists, radiologists, and other specialists.

A reason sometimes advanced against the establishment of regional centres for children is that parents will have to travel further when visiting them. This difficulty can be reduced by allowing unrestricted visiting and providing accommodation for mothers to stay in hospital. Furthermore, children in the regional centre are there because of the severity or nature of their injury, and their parents accept the inconvenience in the knowledge that their children are getting expert treatment not available nearer home.

Two special types of injury need further consideration: burns and scalds, and head injuries. Many of these can be dealt with locally, but others must go to the regional centre because of the specialized surgical and nursing techniques required. Severely burnt children need medical and surgical supervision throughout the whole 24 hours, with precise biochemical and haematological control. Renal dialysis may be needed. Infection may be a complication. The child-psychiatrist may help to prevent or deal with the withdrawal symptoms which frequently occur, and the services of the physiotherapist, dietitian, and medical social worker may all be required.

For these reasons special units for children with burns or head injuries should usually be provided in the regional paediatric centre. If such units are not practicable, the closer the children's centre is to the wards where the children with burns or head injuries are cared for the better will be the liaison between paediatricians and surgeons, which is the key to satisfactory care.

III. Accident and Emergency Services
(Casualty Departments)

The arrangements for injured children in outpatient departments are generally less satisfactory than those for inpatients. Children's hospitals—that is, general hospitals catering solely for children—are often too small to have casualty departments well-enough staffed to be efficient, while, on the other hand, few accident and emergency departments in general hospitals provide the necessary special facilities for children, nor do they usually have medical and nursing staff with paediatric experience.

The aim of outpatient care, as with that for inpatients, should be to provide the best medical attention with the minimum of emotional upset to the child. To achieve this:

(*a*) The medical, nursing, and auxiliary staff who deal with children should be trained and experienced in paediatric techniques. This should apply throughout the 24 hours and seven days a week.

(*b*) Paediatric advice and help should always be available at both consultant and registrar level.

(*c*) Unnecessary delays should be avoided. When the child arrives at the hospital, treatment, or admission if indicated, should be immediate and not after a long, tiring, and perhaps harmful delay. The reception area should be near to the children's unit, and thus minimize the time seriously injured patients have to travel.

(*d*) Children should be shielded from unpleasant sights and sounds, such as severely injured, noisy, or drunken people.

In the district general hospital the accident and emergency department should have a separate entrance and separate waiting space for children so that they will not come into contact with seriously injured adults; there should also be children's examination and recovery rooms, appropriately furnished. The paediatrician should work very closely with the surgeon in charge of the department, and should be consulted about the planning and organization of the department.

The children's accident unit associated with the regional paediatric centre should provide a full accident and emergency service for children. In those regions where the centre is part of the main hospital campus it will sometimes be convenient to place the children's accident unit close to the adult accident unit so that operating-theatres and other services can be shared. If a choice has to be made, however, it is preferable to site the children's accident and emergency service close to the children's inpatient unit. In view of the high proportion of poisonings which occur in children, the regional poisons bureau might well be sited at the children's accident unit.

As in all units, whether medical or surgical, the quality of the work done in the children's accident unit will depend on the degree of supervision by senior staff. The consultant in administrative charge should be responsible for ensuring that the junior staff have adequate teaching, supervision, and support, and that an experienced doctor is always available to receive the seriously injured child. Jones *et al.* (1966) have published a report on the work of a children's casualty department, and their conclusions about the advantages to children of such a department strongly support our own.

Research

The cost to the nation of accidents in childhood must be enormous, yet surprisingly little co-ordinated research is being carried out.

Aspects requiring further investigation include the following: (*a*) accurate estimation of the size and nature of the problem, particularly in relation to non-fatal accidents; (*b*) the family and community relationships of accidents in childhood (Backett and Johnston, 1959); (*c*) the physical, psychological, and educational antecedents and sequelae; (*d*) the biochemical and pathological effects of trauma in childhood, together with the day-to-day management of injured children; and (*e*) "operational research"—that is, a critical evaluation of methods and techniques and their results, and of the organization and efficiency of accident services.

The regional accident unit should act as a centre for the dissemination of information about accidents. It should also maintain a close liaison with statutory bodies and voluntary societies, both national and local, that are interested in the whole problem, and particularly in accident prevention. The large subject of accident prevention is at present being considered by the Medical Commission for Accident Prevention, and is not discussed in this memorandum.

Conclusion

Too little thought has been given to the special needs of the injured child. In 1962 the Standing Medical Advisory Committee of the Central Health Services Council produced a report on the Accident and Emergency Services. This important blueprint for the future did not consider services for children, and indeed only once mentioned the special needs of children. The President of the British Paediatric Association wrote to the *British Medical Journal* (Harris, 1963), drawing attention to this omission and the disparity between the report and that on the Welfare of Children in Hospital (1959). In reply, Sir Harry Platt, who had been the chairman of both committees, stated: "The Report on Accident and Emergency Services presents no challenge to the now widely accepted recommendation of the Report on the Welfare of Children in Hospital." He went on to say, "It is important, therefore, that the paediatricians should support their colleagues (in particular, the orthopaedic surgeons) in seeing that separate accommodation (both inpatient and outpatient) for children is provided in all such plans" (Platt, 1963). We hope that Sir Harry Platt's advice will be acted on, and in this memorandum we have tried to show how it can best be done.

RESEARCH IN PROGRESS

M.R.C. Rheumatism Research Unit

On 26 June the Medical Research Council's Rheumatism Research Unit held an open day for the press. The unit, whose honorary director is Professor E. G. L. BYWATERS, is housed at the Canadian Red Cross Memorial Hospital at Taplow in Berkshire, and was opened in 1947; it was taken over by the M.R.C. in 1958. Much of its work is concerned with studying and treating chronic rheumatism and other connective diseases in children and adults, while the research programme is largely orientated towards related immunological problems.

Juvenile Rheumatoid Arthritis

Dr. BARBARA M. ANSELL described some of the problems of treatment of juvenile arthritis, pointing out that this aimed to leave the patient with a minimum of residual damage once the activity of the disease had died down. Three main principles were involved: the overall management of the patient and the prevention of deformities; the intelligent use of drugs; and co-operation between the various medical and social organizations concerned.

In treatment serial correction of deformities by splints might be necessary, and various plastics for making the latter were being tried out. Hydrotherapy played a valuable part in treatment, as did physiotherapy, which had to be individually planned for each child. Dr. Ansell considered that salicylates were still the safest and the most effective drug available, while if corticosteroids had to be used the aim should be rapidly to try to get the dose down to a minimum level, possibly by adding salicylates as well. Failure to grow in height had been found to be a major problem of long-term corticosteroid therapy. This was not reversed by the addition of either human growth hormone or anabolic steroids, though there was some suggestion that giving the total corticosteroid dosage on one occasion every two days might overcome the failure of growth. Cataract formation had been found to occur in about 10% of all patients treated with corticosteroids, and a trial was in progress to see if this regressed once treatment was stopped.

Concluding, Dr. Ansell emphasized that a large number of social services might be called in to help patients with juvenile rheumatoid arthritis, both when they were in hospital and when they returned home. These included special schools, suitable training for employment, and modifying equipment in the home.

Studies in Autoimmunity

Discussing recent work on autoimmunity, Dr. L. E. GLYNN pointed out that conditions resembling human thyroiditis or allergic encephalitis could be produced in laboratory animals. In rabbits immunized against human fibrin the injection of human fibrin into the knee joints produced a condition with many features similar to rheumatoid arthritis in man, including loss of cartilage and the formation of pannus with lymphofollicular cellular aggregates. A similar lesion could also be produced in about 5% of animals immunized against their own fibrin. This reaction might persist for six to nine months, a finding that suggested that the animal had become immunized to the inflammatory exudate itself, so that the process became self-perpetuating. This hypothesis had been supported by finding that chronic arthritis could be produced by the injection of inflammatory exudate into the joints of animals already immunized against the exudate.

Allergic Orchitis

With Dr. P. C. BROWN, Dr. Glynn had also studied the mechanism of autoimmune damage, using allergic orchitis in guinea-pigs as an experimental model. This could be produced by immunizing the animals with guinea-pig testis and Freund's complete adjuvant, and was characterized by the appearance of delayed sensitivity on the fifth day, of circulating antibody on the seventh to the ninth day, and of histological lesions on the tenth day. If, however, the nature of either of the immunizing agents was changed orchitis did not result, and subsequent work had suggested that this would occur only if both delayed hypersensitivity and circulating antibody were present.

Autoimmune Haemolytic Anaemia

Another experimental model, which had been studied by Dr. E. J. HOLBOROW and Dr. A. M. DENMAN, was the autoimmune haemolytic anaemia that occurs spontaneously in New Zealand black mice. Their findings suggested that an abnormal antigen in the tissues of these animals was providing an autoimmune stimulus to the lymphocytes, the plasma cells, and the tissue cells. Recently electronmicroscopic studies had shown the presence of particles resembling murine-leukaemia virus in the tissues of these animals, and it was possible that these were producing the antigenic stimulus. Antilymphocyte globulin given to young animals had been found to suppress the occurrence of the haemolytic anaemia, though it did not affect the established condition in older animals.

Immunofluorescent Methods

The diagnostic use of immunofluorescent methods in patients with autoimmune disease was discussed by Mr. G. D. JOHNSON. For example, these methods had been used to distinguish between patients with systemic lupus erythematosus, whose sera contained antinuclear factor, and patients with " lupoid hepatitis," whose sera contained, besides antinuclear factor, antibodies directed against renal glomeruli, smooth muscle fibres, and bile canaliculi. One problem that was being tackled at the present time was the international standardization of immunofluorescent methods for diagnosis.

Fluorescent-antibody techniques had also been used by Dr. G. LOEWI to demonstrate the presence of chrondromucoprotein in tissues. Strongly positive results had been obtained in cartilage taken from foetuses and the newborn, but only slight fluorescence had been found in adults.

Collagen and Mucopolysaccharides

Because of its large molecular weight and complex structure collagen would be expected to be a powerful antigen, but, as Dr. J. A. KIRRANE and Dr. GLYNN pointed out, the reverse was true, possibly because of its low content of tyrosine. Nevertheless, the antigenicity of the collagen molecule was greatly increased if it was enriched with tyrosyl or acetyl residues, and this treatment enabled an antibody to collagen to be prepared. They intended to use this to study the normal metabolism of collagen and to see whether it was affected in diseases such as rheumatoid arthritis.

Dr. J. E. SCOTT had studied the distribution of mucopolysaccharides in human cartilage. In infant cartilage virtually no keratosulphate was present around the cells, but its content increased with age, replacing chondroitin sulphate. He suggested that in older subjects this change might lessen the capacity of cartilage to act as a " shock-absorber."

NEW APPLIANCES

Suction Holder for Insertion and Removal of Contact Lenses under Visual Guidance

Dr. J. DALLOS, medical officer in charge of contact lens department, Western Ophthalmic Hospital, London N.W.1, writes: Some persons are unable to handle their contact lenses manually. The first device to help these was introduced in the early 1930s by O'Rourke, and this was adroitly modified by Ruben to suit corneal lenses. However, both instruments are bulky and of use only for insertion of the lenses. A device as small as the ubiquitous rubber sucker, but which accords visual guidance to the contact-lens wearer—both for the insertion and for the extraction of corneal lenses—is now available for the handicapped; in particular, for aphakics and hypermetropes, and also for some other high ametropes who cannot see the lenses once their glasses are removed for insertion; for those who lose control of their direction of sight without firm fixation (one-eyed people, and many others); and for people with clumsy fingers, with small space of lids, etc.

Loose and flabby lids and deep orbits may make routine manual removal of corneal lenses difficult if not impossible, and the often unmanageable difficulties with the blind rubber sucker are resolved by this new instrument. Its size and shape are no different from those of the established sucker, so it is easily carried in any contact-lens case in the space provided. The difference is a rigid transparent collimator rod inserted in its axis, loose at the business end so as not to interfere with suction, and with a hermetically closed opposite club end formed into a lens, which is just jutting out to collect enough illumination from a bright object to maintain a spot of light for guidance, whether the instrument is held loose or is squeezed for suction. Occlusion of the companion eye is automatic, as the other hand is held across the face and spreading the lids apart for action.

WITHOUT PREJUDICE

I suppose that any medical man who has given any thought to the problems of the N.H.S. will be biased in his conclusions on any one of them. There have been so many rapid changes of scene—social, economic, political, national, as well as changes in the development of medicine. Often enough the problems of today are viewed with the prejudices of yesterday. I am sure, for example, that much of the controversy over the payment of G.P.s has arisen because it has related to conditions of practice that are rapidly becoming outmoded by the advance of medicine and the expectations of an informed public.

Unfortunately other elements enter that confuse, and often exacerbate, the issue—and it doesn't really matter what the issue is. The socialist doctor will go all out for a salaried service because of his political beliefs. The fact that socialists like it and advocate it doesn't mean that it is wrong. The Conservative doctor will favour a free-enterprise approach based on payment of fees and competition. The fact that Conservatives like this system doesn't mean that it's right. Their motives are as much political as the motives of the socialist doctor, as much political as medical. They will both assert that what they advocate is in the interests of "good" medicine. The Liberal will try to steer a mid-way course, with a strong political bias against the usurpation by the State of the duties and responsibilities of the individual.

* * *

As we are all political animals, it is therefore not possible to take "politics," that is party politics, out of medicine. Those who protest loudly that politics should be taken out of medicine really mean the other man's politics. Orthodoxy, said F. E. Smith, is my doxy and heterodoxy is other people's. Politics is about power, and, as there is no power so powerful as money, then what doctors are paid and how and by whom is bound to be a political matter. So doctors in this respect have to play politics, medical politics. If the B.M.A. as a medico-political organization did not exist it would be necessary to invent it. Its job is to do the medico-political work for the medical profession. It is in fact, if not in constitution, the medical trade union. Aneurin Bevan knew this. He may have meant to make a bit of mischief when he said at a fork luncheon with the B.M.A. Council, years ago, "I have just come from the Royal College of Surgeons, where everyone is too polite to talk about money. How nice it is to meet people like you who are not ashamed to mention such an indecent subject."

I admit that the medical profession has at times been too obsessed with the subject. Unfortunately obsession, a natural obsession, with money has often determined the attitude of doctors to new ways of doing work that some people think are an improvement on the old. I have often thought that if only methods of work could be examined objectively first, without reference to money, then payment and its methods would in the end sort themselves out. The intensive care for, say, a case of coronary thrombosis has been introduced on the basis of what the proper care is. If this has to be provided in a specially equipped unit such matters as the rights of the doctor as an individual contractor in this context are irrelevant.

Having watched a great friend of mine come successfully through a severe cardiac crisis and a close relative through a pretty desperate status asthmaticus, both as a result of the intensive care available through the efforts of a group of skilled persons, I can have no doubt of the correctness of the verdict of the Association of American Medical Colleges, under the direction of Dr. Lowell T. Coggeshall in 1965. "There is no clear alternative to the organization of the modern practice of medicine as a team effort—and the doctor must be trained specifically to function as leader."

* * *

The evidence piles up, but the English voice is still confused. I find it easier to clear my own mind by looking at the American scene. First of all they are mentally far more adventurous than we are. They are less hide-bound by outdated preconceptions. I have a feeling too that what they do today we shall do tomorrow, as we are much less revolutionary than we like to believe. Nevertheless, I got quite a shock when I read a leading article in the *New England Journal of Medicine* for 25 May which in effect sounded the death-knell of general practice.

"It is probably true," the leader states, "that the physician can function no longer as a general practitioner able to provide total care for his patients under all circumstances." The leader criticizes the suggestion in the report of the Citizens' Commission on Graduate Medical Education that there be a "specialty in comprehensive care" as "somewhat at variance with the concept of elimination of general practice." The leader goes to the heart of the problem with a home-truth everyone is doing his best to ignore: "A role whereby the physician will care for the patient between illnesses and during convalescence is unlikely to appeal to medical students no matter how vigorous the propaganda."

The *New England Journal of Medicine* sees teamwork—group practice—as the proper and efficient way of medical life in a technologically advanced community. "Medical teamwork and close co-operation with paramedical workers leaves little place for the physician specialized in comprehensive care. Much of his work, in fact, may be assigned to a physician's assistant, or to the public-health nurse or social worker." Any scheme for the reform of general or other form of practice must, to my mind, stand or fall by one criterion: Does it afford a fully qualified medical man TIME to do his work efficiently —TIME to examine his patients ? If it doesn't it is almost worthless, even dangerous.

* * *

In the House of Lords debate in February this year Lord Platt made a strong and effective plea for the generalist, and saw the G.P. working in a group practice after the end of his training. So Americans and Britons both agree that group practice, or health-centre practice, is the necessary sequence to strictly individualistic work. Lord Platt went a bit further in the American direction when he said, "Within the group there will be some kind of specialization. A man who has done paediatrics in hospital will take most of the children's work." And I hope the group will include someone thoroughly trained in psychiatry.

We shall move more slowly than the Americans, but I believe that the logic of the situation will mean groups of specialists working in group practices or health centres, with other health workers acting as responsible partners with them. The *New England Journal of Medicine* considers it an error to look upon "specialists [as] somehow incapable of viewing the whole patient, but instead must focus only on a specific organ system. Any good physician is aware of all the ramifications of illness in his patient, and this is continually emphasized in the education of medical specialists."

I suppose Lord Horder was one of the last of the great general practitioners. It is becoming almost impossible for any one man, save the occasional genius, to do the comprehensive work of a general physician—a G.P. There is just not enough available talent of the order required. It is much easier to be a specialist. But a specialist has to study one subject in depth, and when we go to the repair shop we want to have the works put right by a man who really knows what he is doing, by an expert. And this is what the patient will demand. Doctors, after all, exist to look after patients. So I hope that general practitioners in particular will concentrate on the efficient ways of providing medical care in our advanced society, and *then* and only then go into the modes of payment, as the house agents say, subject to contract.

Common Market—a Challenge, Not a Danger

Sir,—In his report on a meeting with the General Medical Council about the implications for the British medical profession of United Kingdom entry into the European Economic Community (*Supplement*, 13 May, p. 85) Dr. Derek Stevenson said that "the General Medical Council was fully alive to the dangers that faced doctors if Britain entered the Common Market," and later Dr. A. V. Russell commented: "Mr. Kenneth Robinson may be able to encourage into this country a number of doctors from countries in the Common Market, accept them into the N.H.S., and use them to bring pressure to bear on us in the general medical services field."

What dangers, I would like to ask ? Perhaps the danger that a certain number of European doctors would come to Britain for their postgraduate education and stay there if they wished to, without the difficulties they usually have to obtain a permanent registration, and which graduates from Commonwealth universities with comparable skill, experience, and command of the English language never encounter ? Is there something so inaccessible, almost of metaphysical quality, in British Commonwealth qualifications that the holder of a Makerere, Madras, or Saskatchewan medical degree is automatically eligible for permanent registration, whereas the mere thought of extending the same privilege to a Paris, Heidelberg, or Padua medical graduate raises an outcry and is defined as a danger by the G.M.C. ?

I also find disturbing Dr. Russell's suggestion that Common Market doctors might be used as blacklegs by your Ministry of Health in order to weaken the bargaining power of British general practitioners. It may be interesting for your readers to know that general practitioners in Italy—namely, the poorest country among the six—have an average monthly income of £400 to £500. I am quite sure that there is only one incentive which might draw a number of doctors from Europe into Britain, and this is the high scientific standard of your medicine, though I fail to see why their absorption in your medical services, and particularly in your hospital establishment, should present more problems than in the case of Commonwealth doctors.

Moreover, one should not underestimate the possibilities of a movement from the United Kingdom to Europe. Why should British doctors emigrate to Australia and Canada and not to Cannes or Cortina ? The fact that there was no uniformity of clinical and scientific standards between the medical professions of the six was never described by any of the national medical bodies as a danger for the professions they represent but as a problem to be solved. They solved it once they decided to face the question realistically from a European perspective. This meant a gradual and progressive application of the Treaty of Rome to the practice of medicine in Europe.

I hope that the attitude of the General Medical Council and of some of the speakers at the B.M.A. Council does not reflect the views of British public opinion. If it does one has to conclude, rather reluctantly, that General de Gaulle is not altogether wrong.—I am, etc.,

S. R. SCAGLIOLA.

Ospedale Civile,
Brescia, Italy.

Enzyme Activity and Cervical Carcinoma

Sir,—The conclusion of Dr. J. T. Boyd and his colleagues (24 June, p. 785) that cytological examination of the vaginal secretions is a much more reliable method for diagnosing pre-invasive cervical carcinoma than measurement of pentose pathway enzyme activity is one with which we are in complete agreement. In fact, this is no more than a repetition of what many workers[1-8] on both sides of the Atlantic have repeatedly emphasized, and that since ". . . increased glucose metabolism via the pentose route and consequently increased activity of its enzymes occurs in many physiological processes as well as in non-malignant pathological conditions . . . it is not possible to relate the degree of activity of the dehydrogenase enzymes to a specific aspect of the biochemical process. Furthermore, since many other factors may influence activity of these enzymes, a test of this nature could not be of diagnostic value in neoplasia."[2]

6-Phosphogluconate dehydrogenase activity in vaginal secretions is, admittedly, not the only topic discussed in this article, but the development of a quantitative enzyme test, as a practical alternative to cytology, provided the impetus and was the authors' stated *raison d'être* of a survey undertaken in over 4,000 women.

Large series and detailed statistics should not obscure the fact that prior consideration of biological variation would have both predicted this outcome and proved the point with many fewer cases.

Alas, the large numbers have failed to drive home the point, for the authors still conclude that ". . . a final assessment of the role of biochemical tests in cervical screening must await further clarification of the natural history of carcinoma-in-situ."—We are, etc.,

Haematomas of the Abdominal Wall

Sir,—Your leading article (17 June, p. 716) reminds us of the case histories of two young, hard-working bowlers, both of county status.

Both initially complained of vague discomfort over the left rectus abdominis muscle, but there were no clinical signs. Both after periods of some weeks developed visible and easily palpable hard swellings in this region. Both were treated surgically. In one the haematoma was evacuated and the muscle tear demonstrated through the fleshy fibres of the lower medial half only of the muscle, the lateral half being undamaged. This bowler, a slow spinner, gave up professional cricket for other reasons and his functional end-result as a cricketer could not be assessed.

The other, a fast bowler, presented with the same symptoms, but again without signs, and after an interval of many weeks developed a haematoma. Again only the medial half of the left lower rectus was torn apart. A repair of the divided muscle was attempted but was technically unsatisfactory, for the divided fibres were inturned and adherent, so that a gap of 1 in. (2.5 cm.) had to be "cobbled." This bowler has now reached test-match status and has since bowled very hard for several years. In both men the rectus sheath was intact—hence the hard rock-like nature of the swelling, which may suggest an alternative and more serious diagnosis.

Two lessons we have learnt may be of interest to others. Firstly, the body's back swing of a bowler as he winds up just before delivery puts a great strain on the leading rectus abdominis muscle—that is, both were right-hand bowlers and in both the left rectus was involved. Mr. Alec Bedser has advised us that the "wind up" of the trunk in young bowlers should be very slowly and progressively developed with a smooth rhythm in their approach to the wicket—and he should know. Secondly, bowlers, particularly six-days-a-week professionals, presenting with vague discomfort over the rectus abdominis should be completely rested from bowling until all discomfort goes.—We are, etc.,

A. L. D'ABREU,
WILLIAM GISSANE,
Hon. Medical Officers,
Warwickshire County Cricket Club.

Accident Hospital,
Birmingham.

SIR,—I would like to comment on the leading article (17 June, p. 716) "Haematomas of the Abdominal Wall."

One meets this condition from time to time in general surgical practice, and it is, I think, important to try to make this diagnosis whenever possible, thereby avoiding laparotomy. In my experience this condition is frequently associated with cough, and it is a fallacy to believe that the mass remains palpable after contraction of the abdominal muscles. This only occurs if the haematoma should extravasate through the rectus muscle and lie anterior to it. In my experience this has not occurred, and the haematoma remains strictly localized to the rectus sheath posterior to the rectus abdominis. The mass may not become palpable until an examination is conducted under general anaesthesia. Indeed, the condition may not be recognizable until an incision is made, because of the extreme mobility of such a mass under general anaesthesia with relaxants. However, usually the condition can be diagnosed because it is associated with attacks of coughing. I agree that bruising does not appear for at least ten days.—I am, etc.,

P. L. BERGER.

Good Hope General Hospital,
Sutton Coldfield, Warwicks.

Experiments on Man

SIR,—I too was pleased that you chose a physician of great intellectual honesty and moral integrity, in the person of Professor L. J. Witts, to review Dr. M. H. Pappworth's book *Human Guinea Pigs* (10 June, p. 689).

I also firmly believe that these qualities apply equally to Dr. Pappworth himself, and, while many might not agree with everything he says (or perhaps the way in which he chooses to say it), let us not deceive ourselves—for most of us know that only too much of what he says is, regrettably, only too true.—I am, etc.,

B. W. ROPER.

Queen Elizabeth Hospital,
Birmingham.

Ophthalmic Graves's Disease

SIR,—We were interested in the letter of Mr. K. C. Wybar (24 June, p. 836) describing the abolition of lid retraction by hexamethonium iodide. Local application of guanethidine eye drops has produced considerable improvement in lid retraction in more than 60 thyrotoxic patients whom we have studied. In our original paper[1] we described the use of 10% guanethidine, but recently have found that a 5% solution is equally effective and produces little if any conjunctival injection.

The role of sympathetic activity in producing lid retraction is indicated by the widening of the palpebral fissure seen following instillation of sympathomimetic amines into the eye.[2] The effect of directly acting amines such as phenylephrine and adrenaline is potentiated by pretreatment with local guanethidine, while indirectly acting amines such as ephedrine or hydroxyamphetamine fail to produce a widening of the palpebral fissure following such pretreatment. Local propranlol fails to influence the width of the palpebral fissure,[1] which suggests that it may depend on α- rather than β-receptor activity.—We are, etc.,

Drugs and Driving

SIR,—The letter by Dr. D. V. Foster (24 June, p. 836) raises important issues and prompts me to record the recent experiences of one of my patients:

Aged 30, she had suffered from a neurotic type depression for two years. I had been giving her tranylcypromine 30 mg. and trifluoperazine 3 mg. (Parstelin) and chlordiazepoxide 30 mg. (Librium) daily for a year as an out-patient which enabled her to hold down a job for which she required a car. She was involved in an accident and considered that her reactions had been depressed by these preparations. On her own initiative she disclosed to her insurance company that she was receiving anti-depressant and sedative tablets. All insurance was promptly suspended unless she could obtain a medical certificate stating that her driving would be unimpaired while receiving these drugs. Since she was unable to get to work by public transport, I was obliged to certify that she had discontinued all medication to enable her cover to be restored. Under these circumstances, should she become depressed again it may be necessary to administer E.C.T.

Insurance companies probably have many similar cases on their records. Thousands of drivers are receiving these and similar drugs on their doctor's prescriptions; but on her proposal form with a major insurance company my patient was only required to testify that she was not suffering from any "*physical* deformity." Perhaps there should now be additional safeguards.

I fully endorse Dr. Foster's conclusion that if we inform our patients that they should not drive while taking the drugs we have prescribed it might cause considerable alarm and would certainly tend to vitiate the "rapport existing between the doctor and patient."

Is there a practical solution? Powerful psychotropic drugs are now available; are there any that are generally regarded as safe to take and drive, and if so in what dosage? Should the popular slogan now be amended to "Don't drink *or take drugs* and drive?" If so most of our patients will have to be passengers.—I am, etc.,

J. C. BARKER.

Shelton Hospital,
Shrewsbury, Shropshire.

Choledochoduodenostomy

SIR,—This valuable paper by Mr. J. N. Burgess and Mr. H. A. Kidd (3 June, p. 607) is really directed towards the management of two conditions: choledocholithiasis and chronic relapsing pancreatitis.

We personally do not regard choledocholithiasis *per se* as an indication for the operation; pigment stones particularly may exist in a healthy blue thin-walled duct with apparently normal function. We consider that the operation is definitely indicated when the common duct contains infected bile in addition to stones, is dilated, and has thick white fibrosed walls, probably the result of long-standing increased intraductal pressure and infection. Appetite and a sense of well-being rapidly return and bloating and heart burn will usually disappear. The operation is also of value if it is not certain that all stones have been removed, especially where the cholangiogram has revealed stones high up in the hepatic duct. We have two cases where a retained stone can be seen on x-ray but the patient is completely symptom free, possibly owing to the presence of the fistula. A small stoma is almost certain to give rise to retention of debris and must be studiously avoided. Except in one case, we have not seen any trouble in over 200 cases where such a stoma was made.

This case was a male aged 56. Within eight weeks of a choledochoduodenostomy for pigment stones in a dilated duct in association with a large spleen, the patient developed recurrent rigors which were only controlled by ampicillin. At re-operation the stoma appeared to be perfectly satisfactory, but in view of the persisting symptoms the integrity of the common duct was restored. The rigors have ceased.

Pancreatitis as we see it in this country may be sharply divided according to the presence or absence of biliary disease. In the former case, gall stones must be comprehensively eradicated. We have found choledochoduodenostomy most satisfactory when indicated in this respect. In contrast we have been unable to find proof that it is specific in the treatment of non-calculous pancreatitis; indeed, we have one certain and one probable case where pancreatitis has relapsed in the presence of an adequate choledochoduodenal fistula. If bile does pass into the pancreatic duct there is no good evidence that this is in any way harmful.[1] We would certainly agree with Burgess and Kidd that sphincterotomy is rarely indicated. It is a procedure with definite mortality and it should be reserved for those cases where pancreatography reveals an obstructed system with a hold-up at the ampulla.

In general we consider that acute or chronic relapsing pancreatitis should not be considered as a single disease entity but that it should always be related to underlying aetiological factors if these can be elicited, as their elimination will often produce a remission in the patient's symptoms. We should abandon the view that any one operation can be a panacea. It is becoming more and more apparent that the exact surgical procedure employed, where duct obstruction is present, will depend upon the site and extent of the blockage.—We are, etc.,

W. M. CAPPER.
J. E. TRAPNELL.

Southmead Hospital,
Bristol.

SIR,—While heartily endorsing the conclusion of Mr. J. N. Burgess and Mr. H. A. Kidd (3 June, p. 607) that choledochoduodenostomy is the treatment of choice for choledocholithiasis, we would like to comment on their technique. In our series of more than 60 such operations (for several indications) we have not found a two-layered anastomosis necessary, a single layer of interrupted or continuous 00 chromic catgut being used.

We are surprised that in the majority of their cases the common bile duct was sufficiently dilated to allow a 2-cm. transverse incision (producing about a 1.5-cm. stoma after two-layered anastomosis) and also surprised that with a stoma that size they had no cases of cholangitis. On preliminary review, our experience is that a 2.5-cm. stoma is advisable, as recommended by Capper,[1] and this can be obtained in most cases only by a longitudinal incision in the common bile duct and a transverse (or, preferably, longitudinal) incision in the duodenum. The importance of the larger stoma seems to be to allow free return of duodenal contents from the common bile duct rather than to prevent stenosis, but we are investigating these points further.—We are, etc.,

Swiss-type Agammaglobulinaemia and Achondroplasia

Sir,—The letter from Drs. R. B. Lowry and J. R. Miller (24 June, p. 842) criticizing the genetic counselling given to the parents of the baby with achondroplasia and Swiss-type agammaglobulinaemia, described in a Clinicopathological Conference published from Hammersmith Hospital (3 December, 1966, p. 1371), calls for a reply. At the time the conference was held it was thought that the agammaglobulinaemia was acquired and that the baby was suffering from classical achondroplasia with little risk of recurrence, but it is now clear that the association is not a chance one (the writer knows of at least four further instances of this combination) and that we are dealing with a new syndrome which is not true achondroplasia nor the usual form of Swiss-type agammaglobulinaemia. In the absence of consanguinity in parents or familial occurrence there is no circumstantial evidence that the condition is due to the expression of a recessive gene, and it is just as likely that it is due to a new and lethal mutation with small risk of recurrence. In the absence of such evidence I feel that it would have been wrong to advise the parents that there would be a 25% risk of further affected children, though they were told that we had not excluded the possibility that this might be the case.

Regarding the previous letter from Dr. V. A. Fulginiti and colleagues (22 April, p. 242), commenting on the same Clinicopathological Conference, I would like to take this opportunity of thanking the authors for their helpful suggestions and for their report of a further case of the syndrome. We had considered the possibility of a runt disease, but this would leave the progressive anaemia that led to the first transfusion unaccounted for, whereas a stem-cell hypoplasia would explain the whole picture. This further example of the concurrence of genetically determined disease of both the bone and bone marrow is of some interest and it would be useful to have the comments of an embryologist on the association.—I am, etc.,

J. A. Davis.

Institute of Child Health,
Hammersmith Hospital,
London W.12.

Treatment of Drug Addiction

Sir,—In the current discussion about the treatment of addiction (20 May, p. 498) there has been little mention of the use of narcosis during the withdrawal phase. It is a regimen which appears to have few advocates, but it seems to have several advantages, especially where opiates are involved. If my small but encouraging experience of it is typical it should perhaps be more widely used. Some of the most seriously handicapped addicts, and those most inaccessible to treatment, either cannot contemplate any reduction in dosage, or, having been persuaded to make some reduction, are so distressed by the withdrawal symptoms that they withdraw from therapy instead. They may simply leave the therapeutic arena, or they may sabotage the treatment by lying about their dosage. In withdrawing this group of addicts narcosis may be the treatment of choice. While compulsory detention might enable more of them to complete their withdrawal, it is not really legal, and, as Dr. P. A. L. Chapple points out (20 May, p. 500), it is not conducive to a good relationship in the more difficult second stage of treatment —keeping the addict off his drugs.

An addict who is withdrawn under narcosis can be assured that withdrawal symptoms will be non-existent, or at most minimal and transient. When he finds that this is so his gratitude and faith may prove useful therapeutic tools later on. Addicts are not noted for their co-operative attitude to treatment; apart from the initial consent, narcosis requires no co-operation. Once begun, it is not at the mercy of his precarious resolve, and since he needs no visitors there is no risk that some of his friends might smuggle drugs to him. Finally, it is perhaps less likely than other methods to deter him from returning for further treatment if he should relapse, as so many do.

Narcosis seems a simple and effective way of managing what is often a difficult and frustrating phase in the treatment of addiction. It has its risks, of course, but they cannot compare with the appalling mortality and morbidity of opiate addiction. It can, and perhaps should, be done in a general medical ward, or in the psychiatric unit of a general hospital with good laboratory facilities.—I am, etc.,

Colin L. Brewer.

Princess Alexandra Hospital,
Harlow, Essex.

Lyell's Toxic Epidermal Necrolysis

Sir,—On 21 June a child 18 days old was seen at her home in Coventry. She had a mild form of this condition. The first sign noticed by the mother had been an infected lesion on the face 4 to 5 days previously, and widespread peeling followed later. A swab was taken that evening and the culture examined on 23 June, by which time Dr. J. Jefferson's article (24 June, p. 802) had been seen by us. The organism isolated was *Staphylococcus aureus* (coagulase positive), which was submitted to the cross infection reference laboratory of the P.H.L.S. at Colindale, where phage-type determination showed that it was also type 71. In view of her age the child was admitted, not because she was seriously ill, but because we were afraid she might become so. Local and systemic antibiotic treatment was given and the child has already improved sufficiently to go home.

There was no history of contact with persons from Northern Ireland.

We are indebted to Dr. B. T. Thom for his report on the phage-typing result.

—We are, etc.,

J. G. Holmes,
A. C. Kendall,

Coventry and Warwickshire
Hospital,
Coventry.

J. E. M. Whitehead.

Public Health Laboratory
Service,
Coventry.

Sir,—In his article (24 June, p. 802) Dr. J. Jefferson mentions that Holzel and Jacobs,[1] among others, have suggested that haemolytic staphylococci may play a part in the aetiology of the scalded-skin syndrome. He then goes on to say that phage type 71 *Staphylococcus aureus*, which was isolated in nine of his recorded 31 cases, was in his view the cause of the disease. Dr. Jefferson omits to acknowledge that phage type 71 *Staphylococcus aureus* was the organism found by us and regarded as the aetiology of the scalded-skin syndrome. Furthermore, Dr. Jefferson reports that seven of his patients were aged 4 weeks or under.

It has been customary to honour the man who first recognized the condition in the newborn period 90 years ago by calling it von Ritter's disease, or dermatitis exfoliativa neonatorum Ritter. The aetiological association of phage type 71 *Staphylococcus aureus* with Ritter's disease has been previously recognized by Howell and Jones,[2] Parker and Williams,[3] and Benson *et al.*[4] Precisely because of our awareness over the past decade of the special effect of phage type 71 *Staphylococcus aureus* in the newborn did we investigate our older patients for this organism. The problems involved were fully discussed in our paper.—I am, etc.,

A. Holzel.

Booth Hall Children's Hospital,
Manchester 9.

Health Week in Rural Practice

Sir,—I was a little disturbed to note the figures for prevalence of undiscovered glaucoma quoted in the article (17 June, p. 756) "A Health Week in Rural General Practice." In this it was observed that the prevalence of glaucoma was "slightly" higher in the authors' survey than were the figures of Luntz and of Wright as quoted[1] in the account of a symposium held in June 1965.

A more careful study of this account will reveal that the prevalence quoted by Luntz (1.5%) is in no way comparable to that given by Wright (1.1%). The "glaucomas" in the Luntz series are in fact cases listed in Wright's account under the headings " Ocular Hypertension " and " Possible Early Glaucoma," with a combined prevalence of 3%. The Luntz series clearly excluded any cases of true glaucoma, and indeed all patients with any history of previous eye disease. As the authors give no criteria for their diagnosis of glaucoma, it is impossible to say to what extent their findings can be compared with either survey. They certainly cannot be compared with both. The literature of glaucoma abounds in such comparisons of incompatible data.

It is depressing also to note that the deficiencies of a single measurement of ocular pressure as a means of detecting glaucoma still do not appear to be fully appreciated. This aspect of the problem is discussed in the same symposium and more fully in the account of the Royal Society of Medicine's 1966 Annual Symposium on Presymptomatic Screening.[2] It would be interesting to know if the authors have read these papers and are aware of the objections to tonometric screening.—I am, etc.,

" Swallowed " Endotracheal Tube

SIR,—I write to endorse heartily the warning and advice communicated by Mr. J. A. S. Dickson and Mr. G. C. Fraser (24 June, p. 811). I have personally heard of the occurrence of 11 cases of " swallowed " endotracheal tube in recent months—including those dealt with at Great Ormond Street. The accident occurs usually when the resuscitator is relatively inexperienced. The tube slips down the oesophagus either when the proximal end is released preparatory to connecting a supply of oxygen (as suggested by Dickson and Fraser), or when mouth-to-tube intermittent positive pressure respiration (I.P.P.R.) is planned and there is therefore no adapter at the end of the tube. Under the latter circumstance, if the oesophagus is intubated, a sudden movement by the infant, or distraction of the resuscitator's attention, can apparently lead to the mishap. I suggest that the most satisfactory precaution would be for the manufacturers to build a solid plastic hook into the posterior wall of the tube, about one inch (2.5 cm.) from the proximal end. Until a tube modified in some such manner is obtainable it would be preferable that the tube be fitted with an endotracheal adapter as part of the normal preparation of the resuscitation equipment. The presence of an adapter interferes somewhat with the ease of performing mouth-to-tube I.P.P.R., but the safeguard is obviously necessary until a modified tube becomes available.

It always takes time for mishaps of this description to become common knowledge, and one can speculate on the grave implications of this instance. The increasing (and laudable) readiness of residents to intubate a depressed neonate has obviously led to an increased number of times that a tube is advanced down an infant's oesophagus. Has there indeed been an increase in the incidence of perforation of the oesophagus, and of rupture of the stomach due to sudden distension with oxygen or air ? It is important that the occurrence of each of these mishaps does not encourage opposition to the full and proper use of endotracheal intubation in the scheme of neonatal resuscitation, but rather that it helps to promote greater effort in the organization of tuition of residents in the manœuvre.—I am, etc.,

J. SELWYN CRAWFORD.

Research Department of
Anaesthetics,
Royal College of Surgeons of England,
London W.C.2.

SIR,—Mr. J. A. S. Dickson and Mr. G. C. Fraser (24 June, p. 812) have performed a valuable service in drawing attention to the ease with which a neonate may swallow an endotracheal tube that has been placed in the oesophagus. They state, " Where junior staff are to be responsible for resuscitation of the newborn it is essential that they should be trained in endotracheal intubation by practising on stillborn infants." I think that all will agree that practice of this kind is highly desirable, but it is sometimes difficult to bring trainee, instructor, and a cadaver together in the same place and at the same time.

For the past six months we have had a Resuci-baby made by Laerdal, of Norway, in use in this department (available in this country from Oxygenaire Ltd.). This model simulates a large baby with a fair amount of muscle tone. It has proved to be most useful in teaching the art of neonatal intubation to anaesthetists, paediatricians, general practitioners, and midwives. Anyone who has become proficient in intubating the model will experience little difficulty in intubating a neonate which is really in need of intubation.—I am, etc.,

Renal Potassium Wasting in Hypercalcaemia

SIR,—We were most interested to read the paper by Dr. P. H. Sanderson (18 March, p. 679) in which he deals with the uncommon occurrence of renal potassium wasting in hypercalcaemia.

A major cause of hypercalcaemia in childhood is vitamin-D intoxication. Ferris and colleagues[1] have described a case of vitamin-D intoxication complicated by renal potassium wasting and tubular acidosis, and reported only two other cases of vitamin-D intoxication mentioned in previously published works . . . " in which unexplained hypokalaemia was associated with an elevated serum calcium. . . . "

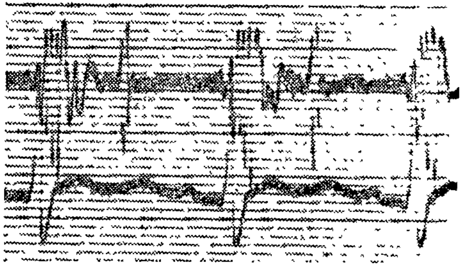
Our experience suggests that renal potassium wasting with hypokalaemia in hypercalcaemia probably occurs more frequently in childhood than is generally realized. In connexion with this we should like to point out some of the cardiographic features which we have noted in a number of cases of the syndrome under discussion. The data obtained from our patients are summarized in the Table below.

Cases 1 to 3 are part of a total of 13 severe cases of vitamin-D intoxication observed in our clinic over the period 1959 to 1964. In all but one of the patients (Case 4) the data were obtained during the first few days of their admission to our clinic, and after a variable period of anorexia, vomiting, thirst, and polyuria.

Case 4 is uncommon for the aetiology of hypercalcaemia and for the evolution of the renal tubular dysfunction syndrome: hypokalaemia with chronic excessive renal potassium loss is still present six years after the severe transient episode of hypercalcaemia. Renal biopsy showed interstitial calcification, tubular changes, and calcification throughout the distal portion of the nephrons.

The electrocardiographic records in Cases 1 and 2 showed the combination of the well-known manifestations of hypokalaemia (prominence of the U wave) together with those of hypercalcaemia (absence of the S-T segment, dome-shaped T waves with shortening of the Q-T). This combined electrocardiographic pattern (see Fig.) is not reported in the published literature on the electrocardiographic changes in electrolyte disturbances.

In Case 1 the phonocardiographic record (see Fig.) also showed the shortening of the dynamically effective mechanical systole identified by the graphically recorded second heart sound (0.18 sec. against 0.22 sec. for the same R-R period in controls). The standard value of the duration of the mechanical systole for the various R-R intervals was deduced from the study of 645 normal children.



The shortening of the mechanical systole was absolute, and was not relative only to the electrical systole identified by the end of the T-wave. The data thus obtained were consistent with the diagnosis of energetic-dynamic cardiac insufficiency (Hegglin syndrome),[2 3] a factor rarely considered in paediatric cardiology.[4]

Case No. and Sex	Diagnosis (Vitamin-D Doses U./day)	Serum Calcium (mg. %)	Serum Potassium (mEq/l.)	Plasma Total CO_2 (mEq/l.)	Urinary *p*H	Urinary Potassium (mEq/24 h)
1 F	Vitamin-D intoxication (300,000) ..	18·6	2·8	26	6·5–7	25
2 F	Vitamin-D intoxication (160,000) ..	16	2·8	24	6·5–7	15
3 M	Vitamin-D intoxication (30,000) ..	15·5	3·1	28	7	21
4 F	AT_{10} overdosage in hypocalcaemic tetany	16	2·5	—	6–7	—

In Cases 3 and 4 the electrocardiographic changes were peculiar to hypercalcaemia and to hypokalaemia respectively, in spite of the combination of the two biochemical disturbances in both of the patients.

Finally, it seems noteworthy that in some cases of hypothyroidism with mild hypercalcaemia, or with a hypercalcaemic pattern of the electrocardiographic record,[5] we failed to note the presence of hypokalaemia and/or an associated electrocardiographic picture of the hypokalaemic type.—We are, etc.,

Autotransfusion

SIR,—I am glad to note that the safe and life-saving measure of autotransfusion has been duly recognized and emphasized in the leading article entitled "Autotransfusion" (13 May, p. 393). No side-effect has been encountered in a series of 332 cases of ectopic pregnancy reported in the *Singapore Medical Journal*.[1] The response of the patients has been found to be satisfactory, gratifying, and oftentimes most dramatic.

I would like to point out, however, that it is not necessary to put any sodium citrate in the sterile collecting flask. The amount of 3.8% sodium citrate solution advocated in your leading article (1 part of solution to 9 parts of auto-blood) is unnecessarily large and may interfere with the blood-clotting mechanism in a patient who requires a massive amount of auto-blood transfusion.—I am, etc.,

DONALD P. C. CHAN.

REFERENCE

[1] Chan, D. P. C., *Singapore med. J.*, 1965, **6**, 23.

SIR,—We would like to endorse the great life-saving value of autotransfusion in the acute ruptured ectopic pregnancy as described in the leading article (13 May, p. 393). For 10 years in a small mission hospital in the West Indies, where ectopic pregnancies are common, we always used autotransfusion. A sterile pack was kept ready for immediate use. It contained two galleypots, a funnel, and a blood-giving bottle together with routine surgical towels, instruments, etc., for a laparotomy. The sterile sodium citrate was purchased in ampoules. On opening the abdomen blood was collected in the gallipots, and using gauze as a filter poured through the funnel into the bottle containing the citrate. Frequently 3 pints (1.7 l.) of blood and sometimes more were returned.

In countries where there is no blood bank and relatives are asked for blood for the patient there is often considerable superstition in donating for the urgent case. The method of autotransfusion is simple and safe and does not require laboratory backing or finances to pay the donors. This method was also used in Government hospitals where the blood bank had but limited supplies.

We do not recall losing one patient with a ruptured ectopic pregnancy, and the number of cases must be well over 100 during the 10-year period.—We are, etc.,

DAVID BULL.
DOREEN BULL.

Warwickshire.

Successful Treatment of Cyanide Poisoning

SIR,—In reporting (17 June, p. 763) the successful treatment of cyanide poisoning with Kelocyanor (cobalt ethylene diamine tetra-acetate), Drs. J. T. B. Bain and E. L. Knowles commented on "the risks involved" in the accepted method of treatment[1] with intravenous nitrite and thiosulphate. We doubt whether there is significant risk in using the accepted method, even in a case where coma may actually be due to cerebrovascular accident rather than to cyanide poisoning. The danger of nitrite-induced hypotension would seem to be more of theoretical than of practical significance. Cases of cyanide poisoning treated in this way usually show a marked improvement in blood pressure, even though the thiocyanate which is produced by the therapy is itself a hypotensive agent. Moreover, the recommended dose of sodium nitrite (0.3 g.) probably[2] produces less than 10% methaemoglobinaemia, and the majority of Chen and Rose's patients recovered with one such dose. They suggested that further amounts may be necessary in severe poisoning, and that up to 1.5 g. could be given without serious ill effects. The fatal dose[2] seems to be about 2 g.

Our experience of one such case has convinced us of the value of Chen and Rose's therapy, and of the dramatic speed with which it takes effect.

A 46-year-old employee in a works where cyanides were used was found unconscious, having been seen well 10 minutes previously. An "egg" of sodium cyanide was found near by. Intravenous nikethamide was given, and he was admitted to the poisoning treatment centre 35 minutes later.

On examination the man was deeply unconscious and not responding to painful stimuli. His breathing was deep and stertorous at a rate of 6 to 8 per minute. He was cyanosed, with a cold clammy skin and a whitish lividity of both feet. The conjunctivae were suffused and cyanosed and the radial pulse rapid and feeble. The blood pressure was unrecordable. No cyanide odour was detected.

His clinical condition was so grave that it was considered necessary to treat him for cyanide poisoning despite the fact that there was only circumstantial evidence for this diagnosis. While a blood specimen was obtained he was given amyl nitrite to inhale. A cuffed endotracheal tube was inserted, without response, and ventilation with oxygen started. This was immediately followed by the intravenous injection of 15 ml. of 3% sodium nitrite during three minutes. When this was completed the respiratory rate had risen to a point which made positive pressure unnecessary. Fifty millilitres of 50% sodium thiosulphate was injected over the next five minutes, by which time the patient was feeling for the endotracheal tube. Ten minutes later it was necessary to remove the tube. Gastric aspiration and lavage were then carried out, and sodium carbonate and ferrous sulphate solutions were left in the stomach. At the completion of this procedure (50 minutes after admission) the patient was fully conscious and orientated. No further injections of nitrite or thiosulphate were necessary.

The man later admitted having attempted suicide by licking a cyanide egg. Rapid absorption of cyanide through the buccal mucosa was consistent with determinations[3] of cyanide and thiocyanate[4] by microdiffusion. Cyanide could not be detected in the gastric aspirate. The plasma level of HCN at admission was 6.1 mg./l.; one hour later this had fallen to a normal basal level (<0.5 mg./l.), but the plasma thiocyanate had risen to 32 mg./l., and remained at a high level for several days. The urinary excretion of thiocyanate reached a peak of 11 mg./l. after four days.

We conclude that until further experience really establishes the efficacy of Kelocyanor there should be no hesitation in using intravenous nitrite whenever there is any possibility at all of cyanide poisoning in an unconscious patient.—We are, etc.,

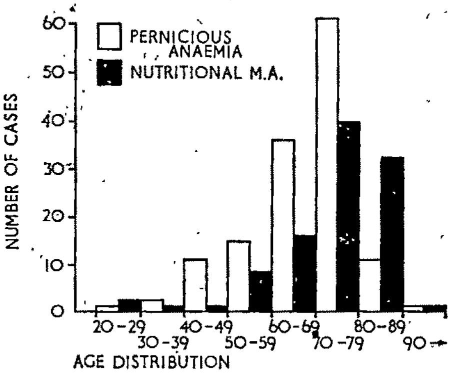
Folate Deficiency in the Elderly

SIR,—The recent articles in the *B.M.J.* (10 June, pp. 652, 667, and 670) prompt us to report our own observations.[1]

Since 1961 in every case of megaloblastic anaemia we have routinely performed both serum vitamin-B12 and folate assays. We found the absolute incidence of both pernicious and nutritional megaloblastic anaemia to be highest in the eighth decade, after which nutritional megaloblastic anaemia (M.A.) was more frequent than pernicious anaemia (see Figure). There was no clinical evidence of malabsorption in any of the cases of megaloblastic anaemia due to folic acid deficiency, and in the vast majority a dietary deficiency was found to be the most likely cause. In a small group of the folate deficiency anaemias a folic acid absorption test[2] was performed, with normal results; following folic acid treatment and dietary improvements no recurrence was observed. We feel, therefore,



that there is a good case for the nutritional origin of these megaloblastic anaemias. The high incidence of pregnancy megaloblastic anaemias in our district, 272 over the same 71-month period, would also support the mainly dietary origin of folate deficiency megaloblastic anaemias.

While in some areas it holds true that pernicious anaemia is the predominant megaloblastic anaemia in the elderly, this does not appear to be the case in our patient material. This does not subtract from the importance of the recommendation contained in the last sentence of your leading article, but underlines at the same time the necessity of an exact diagnosis of the deficiency involved in megaloblastic anaemia in any age group—even in the elderly.—We are, etc.,

Problems of Antenatal Care in the Tropics

SIR,—I enjoyed Mr. S. Haroon's excellent paper "Problems of Antenatal Care in the Tropics" (3 June, p. 617). I feel, however, that the section headed "Admission to Hospital" deserved a more prominent place in his thesis. I should like to comment on two aspects of this problem.

Workers in developing countries must constantly remind themselves that, however much they improve their own local practice, they have a responsibility to the often greater part of the population which so far has not been reached by the maternity services, and for whose confinements there will not be enough hospital beds in the foreseeable future. Thought must be given to a programme that will reach this group and will include mobile antenatal clinics, a domiciliary service, outlying delivery units, and, above all, contact with and upgrading of the indigenous midwife. She will continue to be the only source of aid for village women in many parts of the world for a long time to come, and to dismiss her as a "quack" is not to face reality.

In the second place, when it has been decided that a patient is at special risk and must at all cost be delivered in a hospital, experience has shown that for those whose homes are far from hospital and who for various reasons, often quite beyond their control, cannot be relied upon to attend for admission at the onset of labour a maternity "waiting area" or "village" can be very successful. These need not be elaborate institutions; they are effective when no more than simple structures which may be erected by local community effort near a maternity hospital, at little or no expense to the local authority. Patients may stay here for the last two to three weeks of their pregnancy, cared for by a younger relative who shares the simple accommodation and cooks for the expectant mother. During this vital period the patient is available for antenatal care, for education in health and nutrition, and for immediate admission at the very onset of labour, or earlier should complications supervene.

I feel that at the present stage of communications in the rural areas of many rapidly developing countries, to which Mr. Haroon refers, where the pressure on hospital beds is great and will increase, the provision of such waiting accommodation would do as much as any one other single factor to reduce maternal and foetal mortality.—I am, etc.,

Suppository Treatment of Haemorrhoids

SIR,—I was most interested in the article under "Today's Drugs" referring to the suppository treatment of haemorrhoids (13 May, p. 425). While I agree with your contributor that the use of analgesics should be restricted because of the danger of sensitization, I am somewhat surprised that one of the preparations recommended should contain amethocaine, which is a derivative of para-amino benzoic acid, when it is well known that this group of local analgesic agents is the most likely to produce such sensitization.

I think it might be brought to the attention of your readers that there are two preparations which contain lignocaine as the analgesic agent, a local analgesic which does not produce allergy when repeated with anything like the frequency that happens with the ester group. These agents are Xyloproct Plain and Xyloproct H suppositories.—I am, etc.,

VICTOR GOLDMAN.

Department of Anaesthesia,
Eastman Dental Hospital,
London W.C.1.

Muscle Stiffness and Vitamin C

SIR,—Dr. I. H. Syed has described his experiences in using massive doses of vitamin C to prevent or greatly reduce muscular pain following unaccustomed physical exertion (30 July 1966, p. 304). We have carried out a double-blind trial to assess the effect of vitamin C on 47 volunteer oarsmen from two Oxford colleges, one London school, and from one club crew.

The trial covering 11 days consisted of two periods of four days each separated by three "free" days. On the first day of each four-day period strenuous circuit training was performed and five tablets containing 500 mg. of vitamin C or a "dummy" identical in size, colour, and shape were taken, three during the day with meals and one before and after the "circuit." On the second day three further tablets were taken similar to those on the first day. On the third and fourth days no tablets were taken and no "circuit" undertaken. The two treatments were allocated to the subjects randomly, half taking vitamin C in the first period and the other half having the dummy treatment in the first period. Following the three "free" days the procedure was repeated with the other treatment. The subjects and clinician were unaware of the order in which the treatment was allocated. A questionary was completed by each participant daily (except for the "free" days), indicating the degree of muscular pain experienced, any ill effects, the time since last training, and whether or not the rower felt he had benefited from taking the drug.

Analysis of the results showed no detectable difference between vitamin C and the dummy in the relief of severity of pain irrespective of the order in which the treatments were given. The tentative conclusion drawn from the trial was that vitamin C did not prevent or reduce muscular pain after unaccustomed physical exertion, but possibly the design of the trial was not sufficiently sensitive to detect small differences. One complication was that the first half of the trial affected the second half regardless of the order in which the drug and dummy were taken. There was also some bias due to the length of time since the subjects had last trained. Perhaps the major difficulty, however, is the inherent problem of comparing individual assessments of pain.

We are grateful to the oarsmen and their coaches who assisted in this trial, to Dr. J. M. K. Spalding for advice, to Mr. Breffit and Miss C. Witton-Davies, of the Pharmacy Department of the Churchill Hospital, for assistance, and to Roche Products Ltd. for providing us with "Redoxon" and "dummy" tablets.

Neuro-anatomy

SIR,—The department of anatomy at University College London proposes to introduce courses in neuro-anatomy. It is suggested that two levels are needed:

(1) For those anxious to work in some other field of neuro-biology (for example, neurochemistry); such a course might be for three months.

(2) For those with some knowledge of biology wishing to make serious investigations involving neuro-anatomy; this would be a longer course, perhaps one year.

It would help greatly in planning such courses if anyone interested in either direction would be so kind as to write to me. Such a communication would of course in no way constitute a commitment, but it would be of help to the subject to know how many were likely to be interested, say during the next two years. It is intended to approach the Science Research Council for provision of support for suitable applicants, and it would be pointless to do so without an indication of the level of demand and interest.

May I, through your columns, ask anyone who is interested to write to me at the address indicated?—I am, etc.,

J. Z. YOUNG.

Phenylketonuria

SIR,—A working party set up by the Medical Research Council is conducting a trial of different diagnostic techniques for phenylketonuria. So far, most helpful information has been obtained by studying the newborn siblings of known cases of phenylketonuria, and we are grateful to those who have helped us in this. We are anxious that this work should continue and we would ask any general practitioner, paediatrician, or obstetrician who knows of the expected birth of a sibling of a known case of phenylketonuria to get in touch with: Dr. L. I. Woolf, Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford.—We are, etc.,

ALAN MONCRIEFF.
O. H. WOLFF.
F. P. HUDSON.
L. I. WOOLF.

Radcliffe Infirmary,
Oxford.

Principle of Merit Awards

SIR,—Sir Ronald Tunbridge (24 June, p. 844) states that in any specialty there must be varying degrees of professional competence and skill. This no one will deny, but Sir Ronald goes on to infer therefrom that the rejection of merit awards implies that there are "no differences in the quality of medical practice among general practitioners," and that "23,000 general practitioners are equal in all respects professionally."

With respect, the rejection of merit awards makes no such implication, and surely no one in their senses believes that all general practitioners are equal. What many who oppose merit awards believe is that these awards would do nothing to raise the standard of general practice, but that they would raise the standard of a host of undesirable activities in general practice. For this reason they have been quite rightly rejected by the great majority of general practitioners, and the Representative Body is almost certain to follow the example of the Conference of Local Medical Committees in confirming this rejection.—I am, etc.,

W. B. S. CRAWFORD.

Bath.

SIR,—Sir Ronald Tunbridge (24 June, p. 844) suggests that the country's 23,000 general practitioners imply by their rejection of the proposed merit awards that they believe they are all of equal merit. Any doctor who rejects the proposal on those grounds must be lacking the capacity of self-examination.

It is my belief that the general practitioners have rejected the proposed awards for two reasons:

(1) We do not accept the principle of secrecy in making the awards. If a doctor is considered by any adjudicating committee to have outstanding merit his name should be published within the profession, together with a statement of the grounds on which the award is made. In this way others would be encouraged to emulate his example, and the standard of practice would thus be raised.

(2) Nobody has yet proposed criteria for awards which the general practitioners as a whole consider would, if so emulated, lead to a general improvement in standards among the many different types of general practice conscientiously and effectively carried out in this country.

If secrecy is removed, and satisfactory criteria are drawn up, merit awards will be accepted and welcomed.—I am, etc.,

J. L. RILEY.

Yeadon,
Nr. Leeds, Yorks.

SIR,—As one who voted against the principle of merit awards, I would like to explain my action to Sir Ronald Tunbridge (24 June, p. 844), who believes that the majority of general practitioners are behaving in a ridiculous manner over this. Unfortunately this issue is becoming clouded, and I can understand the wrong conclusions reached by the learned gentleman.

I personally—and I believe many others also—am not against rewarding merit, but if one can clearly define it in general practice it is clear to me that all who are meritorious should receive the same reward. What I and the others voted against was "the principle of merit awards as proposed by the Review Body, and elaborated by the Working Party of the G.M.S.C." To have accepted this would have been to accept that out of 23,000 general practitioners there are 2,600 alone who are worthy of special monetary awards, and that it is possible to select these doctors on a perfectly fair basis.

I cannot accept this, and moreover I do not see how such a scheme could help to raise standards in general practice; there are certainly many better ways of doing this. I *do* see, however, that by a strange coincidence the acceptance of the merit award scheme would satisfy the theory of the Royal Commission that there should be a sufficient variation of incomes in general practice, and this seems to be its main purpose.

The merit award scheme for consultants does not look very satisfactory to me. Is it fair? Has it improved standards? Have we got too many fourth-rate consultants?—I am, etc.,

B. E. COOKE.

Padiham,
Lancs.

Public Health Dispute

SIR,—Your issue of 13 May contained much of significance to public health medical officers. May I make a few comments on one theme? Dr. J. J. A. Reid (p. 432) appears to play down the significance of poor salary rates as a factor in the present decline of morale in the public health service. But in a whole-time service status is closely and overtly related to salary. I remember when the Askwith agreement (1929) was reached the public health doctors were the objects of envy of the other local government chief officers, not excluding the clerks. Since then the salary position of the doctors has deteriorated badly—for which the B.M.A. cannot be held altogether free from blame. At a time when the B.M.A. black-listing appeared to be on the verge of success, in 1949, as soon as the local authorities, being by then in real difficulties about medical staffing, offered to negotiate (at a time they had already agreed the salaries of town clerks and other chief officers) the B.M.A. immediately gave away their most effective weapon, black-listing.

The Ministry of Health's present attitude betokens a sympathy with the local authorities and, it seems to me, a disregard for the welfare of the local health service; a disregard which has been manifest in other ways—namely, (*a*) no support for the suggestion that, when appropriate, medical officers of health should be made honorary members of staffs of hospitals (Guillebaud Report), (*b*) inadequate support for the amalgamation of welfare services with health services, (*c*) inadequate support for medical-officer-of-health membership on executive councils and regional hospital boards, and (*d*) denigration of medical administration.

The salaries of local government departmental medical officers with a maximum of £2,130 are derisory, even in terms of many other local government staff, who have certainly not had their training nor experience nor responsibilities. The salaries of deputy medical officers of health in the smaller authorities are very little better; only in the largest cities and counties does the medical officer of health himself get a salary commensurate with his training and experience. If the B.M.A. wants to protect the living standards of doctors generally it will have to fight hard for public health medical officers. If good doctors are discouraged from entering the service then the organization of preventive health services will decay—to the certain disadvantage of the public.—I am, etc.,

E. D. IRVINE.

Health Department,
Exeter.

Disincentive to Acquisition of Special Skills

SIR,—I wish to call attention to a further disincentive to good general practice and the acquisition of special skills by family doctors.

In 1961, some considerable time before a hospital cytology service in this area was established, I underwent six months' training at King's College Hospital in my spare time so as to be able to screen our own patients for cervical carcinoma. I also did six weeks' intensive study in the gynaecological department there and have since done a refresher course in cytology. With the aid of the Medical Research Council a long-term study of the cytology and sequelae of cervical erosions was begun. A yearly cancer check-up was offered to all women who wished it in our practice, which included a careful clinical examination and cytological screening. Records have been carefully checked and all slides stored against future need for research purposes. The service was free to patients and no payment was received for the work involved. In April 1967 a fee of 7s. 6d. for taking smears from women over 35 once every five years was instituted. This small sum was at least a token acknowledgement that this service was in the public interest.

Two days ago we received a directive to the effect that no fee would be paid unless the slides were examined at the hospital pathology service. One is therefore paid for *not* doing work which has in the past provided a welcome service to some 800 patients a year. The hospital service in turn will suffer from an influx of slides to swell its already overburdened resources. The absurdity of a situation where one is paid not to acquire special skills is self-evident.

Admittedly only a few family doctors will be affected by this decision and one might have expected that those who wanted to continue cytology should produce a certificate of competence in cytology from their training centre, but it is disheartening to realize that bureaucratic regulations can effectively stifle enthusiasm for learning and skill in general practice.—I am, etc.,

UNA M. P. KROLL.

St. Pauls Cray,
Kent.

Democratic Efficiency at the A.R.M.

SIR,—Consideration of the agenda for the Annual Representative Meeting for this year (*Supplement*, 10 June, p. 149) with its nearly 600 items, and the reports one has had of the meetings of recent years, makes one wonder how effective our medical democracy is at present. With a programme of this size it is impossible to hold proper discussions or make useful decisions, even though organization is efficient, the acoustics and weather favourable, the speeches as short as the fashionable mini-skirts, and any blitzkrieg from the junior hospital doctors not too formidable. It is surely time we realized the value of Sir Winston Churchill's oft-reiterated advice "to put all the facts down on half a sheet of notepaper."

There are two changes which, I suggest, might improve things—to ration the number of motions a Division can send up, and to empower the Agenda Committee to prune the programme more ruthlessly. It is well known that some Divisions are more loquacious than others. Study of the agenda shows that at least 29 Divisions, including, I must admit, my own, have submitted more than one motion, with an average of seven, and that nine Divisions have submitted 10 or more motions. In our process of modernization it would surely not be unreasonable to limit each Division to one motion—quality and enthusiasm might improve inversely to diffuseness and prolixity.

At present the Agenda Committee groups together motions on similar subjects and stars one of them. Might it not be better for only the main subjects which could be satisfactorily dealt with in the time available to be listed? More simplification on these lines could cut down enormously the verbosity of the agenda, decrease the great clerical work and expense involved, and decrease the chances of mistakes and overlapping.

Democracy is on trial in many parts of the world. Surely a learned profession in this home of democracy can show an example of modern efficiency in the conduct of its affairs, which are of such importance to every citizen.—I am, etc.,

BRYAN WILLIAMS.

Middlesbrough.

Health Centres

SIR,—I must take issue with Dr. T. D. Richards (10 June, p. 703) on the second paragraph of his letter. If the N.H.S. is to continue providing an unlimited service then this should be the most economical in available manpower. The present system of single-handed or partnership practices does not economize in manpower. Particularly in urban areas there are many "rival" general practitioners, serving the same districts and even the same family. In my view, if an efficient and economic system is to be devised, the alternative to limiting the service available is to provide centres from which a team of general practitioners serve a specific "district." This of course removes the patients' free choice of doctor, and probably means a salaried service.

The remainder of Dr. Richards's letter is most pertinent. The one factor which will save the profession from a salaried service oriented on health centres is the astronomical cost. Undoubtedly the centres would become similar to hospital outpatients, with all the staff working on a shift system. But to talk of collecting evidence to find out if doctors or patients desire health centres is nonsense in the present situation. The problem is not what is desired, but what can be provided for the least money, and in these circumstances the present system is cheapest. When enough practices have organized themselves no doubt the Government will take over, as in 1948, and use suitable premises as centres, which will be cheaper than providing them ab initio.

I must point out that this is not a defence of health centres or a salaried service. Both were envisaged in the original Act, and I believe that the N.H.S. is moving steadily, if slowly, in that direction. The encouragement of group practice is really helping to set up private health centres; machinery for a salaried service is included in the Charter. I personally believe that the patient wants to remain an individual with his own doctor. Much of the present trouble of general practice stems from the attempts to give this service to the public on unlimited demand and free at the time. Nothing could be further from the truth than the premise on which the N.H.S. is founded. It is not an individual's unalienable right to enjoy good health and the best medical care; it is a privilege, and as such must be paid for.—I am, etc.,

H. CAIRNS.

Cardiff.

SIR,—Dr. T. D. Richards writes (10 June, p. 703) that "it is time we started collecting evidence from the patients" about "what proportion . . . in the country prefer health centres to the personal service the good family doctor can now provide in his own consulting-room."

What sort of choice is it that anyone—patient or doctor—makes between something one has experienced and something one has not. Surely only a choice founded on prejudice. The only realistic way of arriving at Dr. Richards's ratio is to ask patients who have sampled both sorts of practice, not "all the patients . . . in the country." Such an opinion poll must of course include not only the patients who have remained in health-centre practices but those who have left such centres to return to orthodox practices, either because they did not care for health centres or because they moved to a district where no health centre existed. Allowance would also have to be made for the fact that there are, I suspect, good and not-so-good health centres, just as there are good and not-so-good practices. Most patients will prefer a good doctor in a well-run practice to a poor doctor in a badly run health centre. In my opinion centres which become "institutions similar to hospital outpatients" *are* badly run.—I am, etc.,

D. S. RACTLIFFE.

Westbury-on-Trym,
Bristol.

East Yorkshire's Memorandum

SIR,—Exception has rightly been taken to an error in our Memorandum on the Constitution (*Supplement*, 3 June, p. 143). The phrase, "The Representative Body, the national forum, is not representative of hospital junior doctors, but the ratio of general practitioners to consultants is approximately correct," should read:

"The Representative Body, the national forum, is not representative of hospital junior doctors but the proportion of consultants is approximately correct."

Consultants form 12% of the home membership of the Association (6,000 in 50,000) and in a Representative Body with 500 members should have 60 seats. In fact they occupy 77.—We are, etc.,

R. L. LUFFINGHAM.
S. T. LUNT.
Joint Secretaries.

Hull, Yorks.

Medical Practice Freedom Fund

SIR,—You were kind enough to grant space in your columns[1, 2] for the publicizing of the above fund. This you may remember was launched in Birmingham, with the object of supporting those doctors who had resigned from the National Health Service. The support was generous; indeed, many of our N.H.S. colleagues are still contributing to the fund.

However, we feel that the fund has now served its purpose, and some restitution must be made to the contributors. Accordingly, a meeting was held at Berrow Court, in Birmingham, on 28 May, of the trustees, committee members, and donors, in order to formulate future policy. Details of the resolutions will be sent to each donor, but, briefly, the proceedings may be summarized as follows:

(1) Contributions by subscribers should be terminated by the end of July 1967.

(2) The borrowers from the fund will shortly be asked to commence repayment over a period of two years.

(3) All subscribers, who have not yet received repayment of their loans to the fund, will be paid an initial 25% of their total contribution, in September 1967.

(4) A further meeting of the trustees, committee, and subscribers, will take place in one year's time, to reassess the financial position.

(5) No more loans are to be granted after July 1967.

In conclusion, Sir, may I express the hope that this letter and subsequent action by their committee will assure the doctors who have subscribed so generously to the fund that the financial position is being regularly reviewed.—I am, etc.,

P. G. JONES,
Secretary to the
Medical Practice Freedom Fund
and Birmingham Action Group.

Birmingham.

Points from Letters

Dispensing in Rural Areas

Dr. K. T. BROWN (Pebmarsh, Essex) writes: I too wish to protest against the mischievous Memorandum on Rural Dispensing. Rural doctors are performing a vital function. . . .

We have here scattered villages served by one bus on a Tuesday and another on a Thursday. Many patients have no cars. However, immediate medical attention is the rule, and often the required drugs are handed over by the rural doctor to the patient in his home. Our patients enjoy so prompt a service that so far I have met nobody who has one good word for the Memorandum. That most certainly includes local members of our Women's Institute.

Obituary Notices

Sir CLAUDE FRANKAU, C.B.E., D.S.O., M.S., F.R.C.S.

Sir Claude Frankau, consulting surgeon and emeritus lecturer in surgery to St. George's Hospital, died at his home near Saffron Walden, Essex, on 29 June. He was 84.

Claude Howard Stanley Frankau, the youngest son of F. J. Frankau, a barrister, was born on 11 February 1883. He was educated at Rugby School and studied medicine at St. George's Hospital medical school. In 1907 he qualified with the Conjoint diploma and the following year became a Fellow of the Royal College of Surgeons of Engand. In 1909 he graduated M.B., B.S. at London University, and also gained the William Brown exhibition. He had gained the Herbert Allingham surgical scholarship in 1908. After the usual house appointments and surgical registrarship he was elected to the surgical staff of St. George's Hospital. When the first world war broke out he volunteered for service and was put in charge of a forward casualty clearing station, where he showed his surgical skill and initiative by operating successfully on many gunshot wounds of the abdomen, performing one of the earliest successful resections of the colon for damage by gunshot. His obvious ability was noted, and he was promoted to the position of consulting surgeon to the Fifth Army with the rank of colonel (temporary). He was thrice mentioned in dispatches, and was honoured by the conferment of the D.S.O. in 1918 and the C.B.E. the following year. In 1921 he took the M.S., and was awarded a gold medal.

Frankau was a general surgeon, but at different times he was in charge of the genito-urinary and the fracture departments of St. George's Hospital. He was for several years lecturer on surgery in the medical school. He was also consulting surgeon to the Waterloo Hospital for Women and Children, Queen Charlotte's Hospital, Woodford Hospital, and the King Edward VII Convalescent Home for Officers at Osborne. In addition, he served as adviser in surgery to the Ministry of Health. Frankau examined in surgery for the University of London, and from 1926 to 1934 was a member of the court of examiners of the Royal College of Surgeons. His high reputation among his professional colleagues was shown by his being elected president of the Association of Surgeons of Great Britain and Ireland in 1937–8 and by his being chosen president of the surgical section of the Royal Society of Medicine in the following year.

In the second world war Frankau was appointed to the very responsible post of director of the Emergency Medical Services for London and the Home Counties. In this position his promptitude, resource, and general administrative ability were outstanding, and it was largely owing to him that the thousands of casualties resulting from the bombing were so smoothly and adequately provided for. In 1945 his outstanding services were recognized by his being knighted.

Claude Frankau was tall, dark, and distinguished-looking. He had a caustic wit, and was adept at deflating pompous persons. Though essentially good-natured and willing to help where help was needed, his outward manner did not always reveal his inward generosity and kindness. While not a prolific writer, he published several valuable articles, including the chapter "Wounds of Joints" in the *Medical History of the First World War*.

Frankau was twice married, firstly in 1914 to Edith Lorne MacDougall (died in 1934), by whom he had two sons and a daughter; and secondly to Isabella, widow of Gordon Cunningham. She died last May.

Lieutenant-Colonel S. R. PRALL
B.A., M.D., I.M.S.(RET.)

Lieutenant-Colonel S. R. Prall, formerly of the Indian Medical Service, died suddenly at his home in Sutton Valence, Kent, on 2 June. He was 76.

Samuel Reginald Prall, son of the late Lieutenant-Colonel S. E. Prall—a well-known "character" in the East, and for many years port health officer in Aden—was born on 18 February 1891. He was educated at Tonbridge School and Emmanuel College, Cambridge, where he held an open scholarship in the natural sciences. After graduating B.A. with honours he entered St. Bartholomew's Hospital, London, for his clinical studies, which were interrupted by the outbreak of the first world war. He spent some months on the North Sea as a surgeon-probationer R.N.V.R. before returning to qualify with the Conjoint diploma in 1915, graduating M.B., B.Chir. the following year. He then took a temporary commission in the R.A.M.C. and served in France and India until 1921, when he received a permanent commission in the Indian Medical Service, in which he remained until the transfer of power in 1947. He proceeded M.D. in 1931.

The last sixteen years of his service were performed on the civil side in the Bombay presidency. He held charge of many civil district hospitals and enjoyed high repute as a good all-round physician and surgeon. As a senior civil surgeon he held charge of St. George's Hospital in Bombay, and he ended his service with four years as civil surgeon, Poona, superintendent of the Sassoon Hospital with its attached medical school, lecturer in gynaecology and obstetrics, and personal surgeon to the Governor of Bombay. A much-respected clinician, he bore an overwhelming clinical and teaching burden through the years of the second world war.

Prall retired to South Africa in 1947, but returned to England after two years and entered into general practice in Kent. He conducted a large and varied practice for ten years, and his vast experience and all-round competence were greatly appreciated. In 1954 he was run over in a road accident and sustained very severe injuries, including a ruptured spleen and colon, a fractured pelvis, and dislocated shoulder, but his brave spirit enabled him to make a good recovery and to return to work, though his competence as a first-class golfer was permanently impaired. He retired to Sutton Valence after ten busy years. In 1918 he married his wife, who survives him with one daughter and an adopted son, to whom our sympathy is extended.—G. R. McR.

H. S. W. writes: I worked under and with Lieutenant-Colonel S. R. Prall for several years in Bombay before and during the second world war, when he had to carry out the duties not only of physician, surgeon, and obstetrician for the men of the old Indian Services and their families but also to administer the large European hospitals, first in Bombay and later in Poona. He was always a sound clinician and an excellent practical and unflurried operator, but above all one was impressed by his great kindness to all those who came in contact with him, from those of the highest rank to the humblest sweeper and his family.

He was a natural games player in his early days, a first-class golfer, and an excellent host and companion. His many friends will always be thankful to have known him and his cheerful family, and will sympathize with them now in their sad loss.

T. PRICE, M.B., M.CH.

Mr. T. Price, formerly consultant orthopaedic surgeon to the Bath clinical area, died at his home in Heswall, Cheshire, on 18 June. He was 53.

Tom Price was born on 2 May 1914 at Connah's Quay, Flintshire, and was educated at Hawarden Grammar School, after which he entered the University of Liverpool for his medical training. He qualified M.B., Ch.B. in 1939, and the same year took the Conjoint diploma. After holding resident posts in Liverpool he joined the R.A.M.C. in 1941, and in spite of the disability of congenital hip trouble he served with distinction for four years, of which he spent three and a half years in India. After demobilization in 1946 he returned to Liverpool, and took the M.Ch. in orthopaedic surgery in 1947. Shortly after this he was appointed to the Bath and Wessex Orthopaedic Hospital, where much of his time was devoted to the children's clinics of Somerset and Wiltshire. When the National Health Service was established in 1948 he was appointed consultant orthopaedic surgeon to the clinical area, and he fulfilled this post with great enthusiasm and efficiency. In 1957 his health began to fail, but in spite of this additional disability he continued to work heedless of the cost to himself. He insisted on sharing the emergency work and the routine with his colleagues, and put his patients' interests above everything else. Eventually in 1964 he was forced to give up and was prematurely retired. He was a member of the British Orthopaedic Association, and was chairman of the Bath Division of the British Medical Association in 1954–5.

Tom Price was a quiet, competent surgeon with a great love for his work and for his patients. He particularly enjoyed " cold " orthopaedics, and with his own disability he established a close relationship and mutual regard with his patients. His name will long be remembered in the counties of Somerset and Wiltshire and by his many friends, young and old alike, in the city of Bath. He died in sight of his beloved Welsh mountains and the beautiful Dee estuary. He leaves a widow, Mary, whose devoted care and companionship enabled him to enjoy his short retirement.—A. E. B.

Ll. RHYS-JONES, M.R.C.S., L.R.C.P.

Dr. Ll. Rhys-Jones, a general practitioner in Aberystwyth, Cardiganshire, died in hospital on 29 May. He was 73.

Llywelyn Rhys-Jones was born in 1893 in Treorchy, South Wales. Before taking up medicine as a career he had intended entering the church, and with this in view he gained a scholarship to St. David's College, Lampeter. From Lampeter he gained a further scholarship to Jesus College, Oxford. His education was interrupted by the outbreak of the first world war, and he was commissioned first in the Royal Welch Fusiliers and later in the King's African Rifles. He served in France and East Africa. After demobilization he returned to Oxford. He had, however, then made the vital decision to abandon his theological training and to qualify as a doctor. Becoming a student at Guy's Hospital, he qualified with the Conjoint diploma in 1925. His first practice was in Brixton, South London, but in 1948 he returned to Wales to practise in Aberystwyth.

His early training in theology and the arts marked him out from among his fellow practitioners. Apart from his work as a doctor his main interest throughout life remained in Welsh literature. He was himself a poet and was proud of his relationship to Ben Bowen, a promising Welsh bard who died when he was a very young man. Dr. Rhys-Jones derived great pleasure from his membership of the Bedol, a small group in Aberystwyth whose primary interest has been in the cultivation of Welsh literature. Yet his main concern rested in his endeavours to relieve suffering. His first thought was for his patient and his family, and nothing was too much trouble for him. His kindness, sympathy, and conscientiousness endeared him to all his patients.

He is survived by his widow, a son, and a daughter.—J. A. W.

J. R. B. RUSSELL, M.B., CH.B.

Dr. J. R. B. Russell, formerly in general practice at Chester, died in Chester Royal Infirmary on 13 May at the age of 79.

John Russell Brodie Russell was born in Edinburgh on 3 May 1888, and was educated at Denstone College. After leaving school he studied law for a year in Edinburgh, but finding it too detached from human contact he went to Manchester University to study medicine, graduating M.B., Ch.B. in 1914. After resident posts at Manchester Royal Infirmary he joined the R.A.M.C. in the same year, serving with the Lancashire Fusiliers, and saw active service at Passchendaele and Vimy Ridge. He attained the rank of major, and was invalided in 1916. After demobilization he came to Chester, where he was initially in charge of St. James's Hospital (now Chester City Hospital). At that time he carried out most of the operations in the surgical and maternity departments. A few years later he joined Dr. J. L. Browne in practice in Chester, continuing with some surgical work at St. James's Hospital for another ten years. When Dr. Browne died in 1935 Dr. Russell continued the practice with the help of assistants until he was joined by his son in 1951. His kindly manner coupled with a quiet humour endeared him to his large number of patients, who were helped by the courtesy and patience with which he listened to their problems. His work was his principal interest, and he kept his knowledge of medicine up to date by diligent reading.

When failing health led to his retirement in 1964 his friends were concerned that he might find it difficult to develop new interests. However, he took up painting with the same energy he had previously devoted to medicine, and rapidly achieved a consistently high standard of production in his own particular manner. His representational style is not now generally popular, but many would have been pleased to emulate his work after a lifetime of application. Although increasingly handicapped physically, he had great happiness from his few years of retirement, which he shared with his daughter, who looked after him devotedly after his wife's death.—A. C. C. H.

JANIE H. McILROY, M.A., D.SC., M.B., CH.B., D.P.H.

Dr. Janie H. McIlroy, formerly honorary senior clinical assistant at the Royal Westminster Ophthalmic Hospital (now Moorfields), London, died at her home in Ayrshire on 21 May. She was 87.

Janie Hamilton McIlroy was born in 1880, daughter of the late Dr. James and Mrs. Anne McIlroy, of Ballycastle, Northern Ireland. After graduating M.A. at Glasgow in 1898 at the early age of 18 she took the B.Sc. in 1901 and the M.B., Ch.B. in 1904. She then embarked on a distinguished scientific career, winning several research scholarships, and becoming D.Sc. in 1911. The following year she took the D.P.H. But her interest now turned to ophthalmology, and after an appointment as assistant medical officer and full-time oculist to the Education Authority, Glasgow, she went to India as lecturer in diseases of the eye at the Lady Hardinge Medical College, Delhi. On her return to Britain she continued with ophthalmic work, and was appointed clinical assistant at the Royal Westminster Ophthalmic Hospital, London, in 1926, becoming chief clinical assistant the following year. Here it was that she worked happily for many years in conjunction with an ophthalmic post in the L.C.C. medical service, retiring with the advent of the National Health Service in 1948. Her cheerful presence and willingness to help made her a most popular member of the clinic in which she worked, and her scientific background showed in the logical way in which she attacked all problems.

Her good humour, patience, and tact endeared her to the patients, and when she retired and left London she was much missed by all. But she is not forgotten by her friends.—G. G. P.

W. H. PARKINSON, M.B., CH.B.

Dr. W. H. Parkinson, a senior assistant medical officer in charge of the maternity and child welfare services in Northampton, died suddenly on 5 June. He was 53.

Wilfrid Hampson Parkinson was born on 15 April 1914, and was educated at the Royal School, Edinburgh, and Edinburgh University, graduating M.B., Ch.B. in 1941. He entered general practice in 1947 and succeeded as principal in January 1949 at Byfield, near Rugby, where he remained the sole practitioner until he was obliged to retire from general practice in 1966 on account of ill-health. In December of that year he entered the field of public health as senior assistant medical officer in charge of the maternity and child welfare service in Northampton, and his sudden death was a tremendous loss to the department. In his short term of office he had shown himself to be an extremely able and competent colleague, scrupulous and diligent in the pursuit of his new responsibilities, to which he had adapted himself with enthusiasm and success. His calm, quiet, and charming manner not only endeared him to all in the department who worked with him but quickly earned him the respect of his colleagues.

His untimely death is a sad and tragic blow, not only to the department, but more particularly to his wife and three children, to whom we extend our deepest sympathies. —W. E.

D. B. STEPHEN, M.B., CH.B.

Dr. D. B. Stephen, formerly in general practice at Enfield, Middlesex, died suddenly at his home in Enfield on 16 June. He was 57.

David Bishop Stephen was born in Aberdeen on 17 March 1910, and received his medical education at Aberdeen University, graduating M.B., Ch.B. in 1937. He first entered practice in Coventry, but his practice was blitzed in the second world war, and he went to Enfield as an assistant to Dr. R. Adam to succeed his twin brother, George, who had been called up. Shortly afterwards he joined the R.A.M.C. and served in Italy, where he was graded as a dermatologist. After demobilization he returned to take up a partnership with Dr. H. P. Warren, while his brother returned to take up partnership with Dr. J. E. Carpenter, both in general practice in Enfield. David later entered into partnership with Dr. P. McCulloch, and became medical officer to the Small Arms factory. His twin brother died some three years ago.

He is survived by his widow, to whom we extend our deepest sympathy.—H. R. S.

News and Notes

EPIDEMIOLOGY

Coroners' Verdicts in Greater London

The seven coroners in Greater London have given the Greater London Council the following information about their verdicts on the 3,641 inquests held in Greater London in 1966. Comparable figures for the previous year exist only for the nine months from 1 April.

Verdict	1966	1965 (Nine Months Only)
Murder	18	9
Manslaughter	3	8
Suicide	992	814
Self induced or attempted abortion	4	4
Lack of care or self neglect	6	6
Chronic alcoholism ..	45	46
Addiction to drugs ..	9	10

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending **17 June** (No. 24) and corresponding week 1966.

Figures of *cases* are for the countries shown and for Greater London. Figures of *deaths* and *births* are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES	1967					1966

† Includes primary and influenzal pneumonia.

§ Includes puerperal pyrexia.

PARLIAMENT

Abortion Bill in Jeopardy

The report stage of the Medical Termination of Pregnancy Bill was unfinished after 12 hours' debate that ended about 10 a.m. on 30 June. Over 200 M.P.s, stayed throughout the night, a measure of the Commons' interest in abortion reform. It must now be considered doubtful if the Bill will get on the Statute Book this session. Even if the Government provides more time and the Bill goes through the Commons, it has still to be conducted through all its stages in the House of Lords.

During the debate the significant change was made of removing from Clause 1 the contentious "well-being" condition. This was done at the instance of the sponsor of the Bill, Mr. D. STEEL (Roxburgh, Selkirk and Peebles, Lib.), and received the approval of the Home Secretary, Mr. R. JENKINS, who has regarded the Bill as a worthwhile and reforming measure that should be acceptable "to a good deal of moderate opinion both inside the House and outside."

With some other related amendments Clause 1, subsection (1)(a)(i) now reads: "That the continuance of the pregnancy would involve risks to the life of the pregnant woman or any existing children of her family."

Questions in the Commons

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Treatment of Drug Addiction

Mr. W. DEEDES (Ashford, Con.) asked the Minister of Health on 26 June what consultations he had had with the London teaching hospitals about future arrangements for treating drug addiction in London.

Mr K. ROBINSON: "General principles of treatment of heroin addiction were considered at two medical conferences of the consultant psychiatrists concerned. Separate discussions took place with each hospital individually. Informal discussions on points of practical application will continue with a group representative of interested London hospital boards."

Mr. DEEDES said that at least one London teaching hospital had grave misgivings about certain aspects of this scheme and doubted whether it would work. Was the Minister sure he was proceeding on the right lines ?

Mr. ROBINSON replied that as far as he was aware there was no general dissent among those primarily concerned about the way they were proceeding. Outpatient facilities were available at nine hospitals in central London, and other clinics would be opened in due course. About 30 hospitals in the London area already provided facilities for inpatient treatment of addicts of all types.

Health Centres

The Minister of Health stated on 28 June that since July 1948, when there were 10 health centres in existence, 36 more had been opened in England and Wales, 30 more were under construction, 28 had been approved, and plans for 48 were under consideration. Present evidence suggested that the 10-year plans of local health authorities for 300 centres by 1976 might be greatly exceeded.

Alcoholism in Scotland

Mr. W. HANNAN (Glasgow, Maryhill, Lab.) asked the Secretary of State for Scotland on 28 June how many patients suffering from alcoholism or alcoholic neurosis were admitted to mental hospitals in 1956, 1961, and 1966 ; and what proportion of the total bed accommodation such patients occupied in those hospitals.

Mr. B. MILLAN, Under Secretary: "The numbers admitted were 732, 1,350, and 2,755 respectively, which constituted 7.1%, 9.9% and 13.6% of the total admissions to such hospitals. For 1966 these figures include admissions to psychiatric wards in general hospitals. I regret that figures are not available for the proportion of total bed accommodation in these hospitals occupied by alcoholic patients. On average, however, their length of stay is shorter than that of other patients in these hospitals."

Mr. HANNAN wanted him to include alcoholism in the considerations of the committee on drug addiction. Mr. MILLAN thought this impracticable, but told him that regional boards had been asked to set up special units to deal with alcoholism and some were already being established.

General Practitioner Service in Scotland

The Secretary of State for Scotland gave the following figures on 26 June showing the total number of doctors working the general practitioner service in Scotland since October 1964:

	Principals	Assistants	Total	Trainee Assistants
1964 October	2,684	106	2,790	44
1965 January	2,680	109	2,789	45
April ..	2,671	116	2,787	44
July ..	2,651	105	2,756	50
October	2,638	90	2,728	46
1966 January	2,618	100	2,718	36
April ..	2,610	105	2,715	26
July ..	2,615	90	2,705	23
October	2,597	78	2,675	33
1967 January	2,594	89	2,683	35
April ..	2,601	85	2,686	39
June ..	2,606	92	2,698	40

Breath Alcohol Tests

Mr. GRESHAM COOKE (Twickenham, Con.) asked the Home Secretary on 22 June what study he had made of the evidence sent to him tending to show that breath alcohol tests could give spuriously high results for as long as 30 minutes after the consumption of alcohol ; and whether arrangements would be made to instruct the police fully about this aspect of the matter.

Mr. ROY JENKINS: "Authoritative investigations have shown that traces of alcohol in the mouth do not ordinarily persist after 20 minutes from the time of drinking. I shall advise the police that this is the minimum time which should elapse between a roadside test and the offer of a second test at a police station."

New Fulham Hospital

Mr. IVOR RICHARD (Barons Court, Lab.) asked the Minister of Health whether he was satisfied with the speed of the development of the new Fulham Hospital.

Mr. J. SNOW, Parliamentary Secretary: "Yes. Initial site works are in progress. The main works, costing some £10 million, will begin this autumn, and the final phase is likely to start in 1972-3. The whole of this major project to rebuild the Charing Cross Teaching Hospital and Medical School and to replace a number of other scattered hospitals is scheduled for completion by 1976."

Emigration of Doctors

Mr. J. BIFFEN (Oswestry, Con.) asked the Minister of Health on 3 July what study he had made of the evidence about emigration of doctors contained in a survey conducted by the Junior Hospital Doctors Association.

Mr. ROBINSON: "This survey was, I understand, undertaken in a single hospital region in order to obtain experience for a wider one, and the results quoted can only be preliminary. I expect to publish shortly the results of my department's work on the emigration and immigration of doctors during the period 1962 to 1964, which will describe in considerable detail the general features of this movement."

The Sexual Offences (No. 2) Bill passed the report stage in the House of Commons and was read a third time on 4 July.

The National Health Service (Family Planning) Act was given Royal Assent on 28 June.

Questions in the Lords

Lead in Water Supplies

LORD DOUGLAS OF BARLOCH asked the Government on 27 June what advice, if any, had been given to water undertakers about the necessity of correcting water supplies that are liable to dissolve lead.

LORD SORENSEN said no general advice had been given, since the normal remedy, treatment of the water with alkali, was simple and well known.

LORD DOUGLAS OF BARLOCH pointed out that a recent survey carried out by the department of civil engineering at Liverpool University showed that in county boroughs with a population of 20m. 95% had water supplies that were liable to dissolve lead. Did not that require attention ?

LORD SORENSEN said his information did not cover that point but added that the use of lead pipes for water was declining and in many parts of the country the practice did not exist.

MEDICO-LEGAL

Court Orders Blood Test

[FROM OUR LEGAL CORRESPONDENT]

A judge of the Probate, Divorce, and Admiralty Division of the High Court has ordered that a child should undergo a blood test with a view to determining paternity (*The Times*, 2 June).

A decision of the Court of Appeal in 1964[1] that the Court had no power to order parties to a suit to undergo blood tests remains unimpaired. The judge in the present case, Mr. Justice Ormrod, in making the order for the test, drew on the jurisdiction of the Court as custodian of the child. He held that the jurisdiction was unaffected by the earlier decision of the Court of Appeal.

The question of paternity arose in June 1965, after a husband had been granted a decree of divorce on the grounds of his wife's adultery with the party cited. There was a child of the wife's who could be the daughter of either the husband or the party cited. The court had ordered that the paternity of the child be tried as an issue. That issue was first argued in June 1966, when it was appreciated that the earlier decision of the Court of Appeal prevented the ordering of a blood test. The husband, wife, and party cited all consented to undergo a blood test, as all wanted to resolve the genuine doubt about paternity. But the Official Solicitor, who was acting as guardian *ad litem* for the child, refused to consent on behalf of the child. In the absence of any other helpful evidence the court would have had to fall back on the presumption of legitimacy and hold that the husband was presumed to be the father. Instead of deciding the matter in this unsatisfactory way the court adjourned the hearing for argument on its custodial jurisdiction.

In the course of argument on the court's powers relative to children in its care, counsel for the Official Solicitor conceded that a Chancery judge in wardship proceedings could order that a ward submit to a blood test but argued that a judge of the Divorce Court did not have those powers. Mr. Justice Ormrod acepted the concession but rejected the argument that a judge in one division of the High Court did not have all the powers of a judge in another division of the court on similar subject-matter. Whether the Official Solicitor's concession was rightly made or not does not appear to have been argued.

Accordingly Mr. Justice Ormrod held that he had the power to order a blood test on the child in the exercise of his custodial jurisdiction, and would exercise it if it was in the interests of the child to do so. On the facts the court considered that in the future the child was bound to wonder who her true father was, and she might suffer great anxiety over the question. Each of the four people concerned in the case would have a better chance of developing a healthy and normal relationship between themselves on the basis of truth rather than on the basis of doubt.

Mr. Justice Ormrod ordered that the child's blood be tested, but only after the three adults concerned had permitted samples of their blood to be taken. On the application of the Official Solicitor a stay was granted on the order, provided a notice of appeal was entered against the court's decision within 28 days.

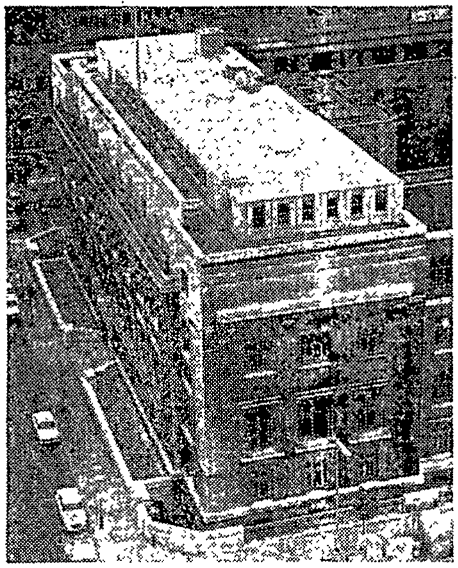
MEDICAL NEWS

Extensions at Keppel Street

On 28 June PRINCESS ALEXANDRA opened the new and reconstructed departments at the London School of Hygiene and Tropical Medicine (see *B.M.J.*, 18 February, p. 441). The gains in accommodation include a new refectory, new premises for the departments of human nutrition and entomology, and an extension of the public health department on a new fourth floor built on the roof. A valuable addition, provided by the Wellcome Trust, is an open-access stack for the library. LORD HEYWORTH, chairman of the court of governors, and Dr. E. T. C. SPOONER, dean of the school, also took part in the ceremony.



Postgraduate Tropical Medical Centre

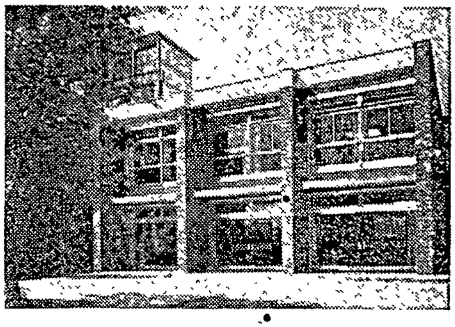
Contributions from Ghana, Uganda, and Zambia in support of the International College of Tropical Medicine were presented at a ceremony held in the Ugandan Embassy in Washington on 1 June, the first anniversary of the incorporation of the college. In accepting the gifts Mr. GEOFFREY MYERS, F.R.C.S., provost of the college, said the council would be deciding later this year where to establish its postgraduate medical centre in Africa (see *B.M.J.*, 1966, 23 July, p. 248). The address of the college is P.O. Box 497, Hamilton, Bermuda.

Medical Research in Scotland

The Scottish Hospital Endowments Research Trust has made a grant of £34,465 over five years to Professor JAMES WALKER, St. Andrews University, for studies of the physiology of pregnancy. Others to receive support for projects are: Dr. MARTIN M. WHITTET, Craig Dunain Hospital, Inverness, study of the epidemiology of alcoholism in the Highlands and Islands, £5,000 over two years; Mr. W. BRYAN JENNETT, Killearn Hospital, Stirlingshire, studies in cerebrovascular disease, £2,950 (supplementary grant); Professor Sir IAN HILL, St. Andrews University, studies in vectorcardiography in heart disease, £1,158 (supplementary grant); Dr. IAN W. B. GRANT, Northern General Hospital, Edinburgh, bronchial asthma, £3,390 (supplementary grant); Dr. STANLEY S. BROWN, Edinburgh University, biochemical study of drug binding in acute poisoning, £6,219 over three years; Dr. ANDREW SNEDDON and Mr. THOMAS HAMILTON, Edinburgh University, ovarian steroidogenesis in relation to human and experimental breast tumours, £4,788 over three years; Dr. D. J. C. SHEARMAN and Dr. D. G. FINLAYSON, Edinburgh University, relationship of gastric carcinoma to pernicious anaemia, £5,104 over three years. The Cruden Medical Research Fellowship for one year has been awarded to Dr. MARJORIE E. M. ALLISON.

Luton Medical Centre

Professor Sir MAX ROSENHEIM, President of the Royal College of Physicians, gave the inaugural address at the Luton and Dunstable Hospital medical centre on 27 June. The centre, which was opened in April, has been built from funds raised locally and with the support of the regional board and the hospital management committee. It consists of two floors, each linked to the main corridors of the hospital. Facilities include a lecture hall with seating accommodation for 160, a lounge, and a medical library. The building and equipment have cost about £40,000.



BRITISH MEDICAL JOURNAL

LONDON SATURDAY 15 JULY 1967

Pointers

President's Address: Mr. Robert V. Cooke addresses the Annual Representative Meeting (p. 129). Leader this page.

Phenylketonuria in Children: Dietetic treatment gives best results when started in early infancy, according to Dr. Barbara Clayton and colleagues (p. 133). Leader at p. 124.

Epidemiology of Tinea Pedis: Miss Mary P. English and colleagues found that infection was transferred by socks in a long-stay hospital (p. 136). Leader at p. 128.

Haemodynamic Response to Squatting: Dr. M. Nellen and colleagues from Cape Town found changes in intensity and duration of systolic murmur an aid to bedside diagnosis (p. 140).

Clotting in Scribner Shunts: Dr. A. J. Wing and colleagues were able to reduce this with long-term oral anticoagulant therapy (p. 143).

Diagnostic Paracentesis: Mr. W. N. W. Baker and colleagues recommend this in blunt abdominal trauma and post-operative complications of abdominal surgery (p. 146).

Stress Incontinence: Mr. Thomas Moore and Mr. P. F. Schofield suggest success of electrical stimulation treatment is due to restoration of pelvic muscle floor tone (p. 150).

Ethacrynic Acid: Hepatocellular damage reported by Professor K. K. Datey and colleagues from Bombay (p. 152).

Case Reports: Sugar consumption related to seborrhoeic dermatitis (p. 153). Biliverdinaemia in indomethacin therapy (p. 155). *Mycobacterium Battey* infection resembling tuberculosis (p. 157).

Today's Drugs: Fenfluramine (p. 159).

Cervical Cytology: Apparatus for automatic preparation and scanning described by Mr. M. M. Beddington and Dr. R. A. Diamond (p. 160)

Pertinax: Without Prejudice (p. 172).

Annual Representative Meeting: First report (*Supplement*, p. 25).

Future President: Dr. J. W. Howie elected President of B.M.A for 1969–70 (*Supplement*, p. 25).

C.C. and S. Committee: *Supplement*, p. 66.

Unity and Service

Concern with each other and concern for the service that medical men and women give to the community is the theme that provided the title " One Profession, One Purpose," chosen by Mr. Robert V. Cooke for his presidential address at this year's Annual Meeting of the British Medical Association at Bristol. It is reproduced at page 129 of the *B.M.J.* this week. Like many other observers of the current scene he has been impressed by the signs of conflict, even disintegration, within the medical profession, and he specially emphasizes the need for " bonds of closer unity " between the family doctor and colleagues in other branches of practice. The twentieth century is indeed a time when, in response to not unnatural impulses, peoples and individuals are everywhere seeking the means to govern themselves. We have all taken to heart Cassius's lesson that the fault is not in our stars but in ourselves that we are underlings, and the remedy is increasingly sought through vigorous political action. But in the righting of old-standing wrongs, old benefits and amities may perish in the ferment. More fortunate than people in many other occupations, medical men and women acquire in their training much besides a technical equipment to do a job efficiently, for the alleviation of an individual's suffering that every member of the profession begins to undertake from the first moment he steps into the wards as a student surely gives all but the most insensitive a deep respect for the human condition—and perhaps its sorrows more than its joys. As the President remarks, the doctor will always be something more than the latest computer, bringing to his job " the highest ethical standards, the deepest sense of personal responsibility, and a readily felt warm humanity."

In calling for unity within the profession Mr. Cooke was making a particularly topical plea, for the Representative Body has lately been much concerned with proper representation in the counsels of the B.M.A. and this year again debated its constitution. Discussion of the details of this debate is beyond our present purposes, but it is worth stressing here that equitable representation lies at the heart of professional unity. The Association has long cherished a reputation for the open manner in which it conducts its affairs and the facility with which any member may put forward his views. Its members are no more restricted to any particular branch of the profession than are its policies the reflection of any particular doctrine. In the much-debated constitution of the autonomous bodies it attempts to reconcile the special needs of certain groups with the obligations that every medical man owes to his membership of one profession. Thus the aim of constitutional change may be thought of as twofold, firstly to provide the means by which true majority decisions are reached, secondly to safeguard the interests of minorities. And the often expressed anxiety that autonomy can go too far if not wisely restricted springs from the ordinary doctor's awareness that membership of a profession entails relationships deeper than those deriving from political self-interest.

© *British Medical Journal*, 1967. All reproduction rights reserved.

Speaking as a surgeon who has devoted his life to this most exacting of crafts, Mr. Cooke has been struck by the real service that a good clinician does his patient by sparing him unnecessary diagnostic investigations and needlessly hazardous remedies. He acknowledges, as any doctor must today, that there are limits beyond which clinical diagnosis cannot go, but "I am sure," he declares, "we should reaffirm our faith in clinical diagnosis, teach it more carefully, recognize that it takes a long time to learn, requiring as it does a great deal of experience, quite apart from a vast amount of knowledge correctly to interpret the story and the physical findings." This is particularly true in relation to the many underdeveloped parts of the world for which British medical schools have taken on educational obligations.

Phenylketonuria

In 1934 A. Følling[1] discovered phenylpyruvic acid in the urine of 10 mentally deficient patients. Ferric chloride reacts with phenylpyruvic acid to produce a greenish-blue colour, and the addition of a small amount of a ferric chloride solution to the urine is the standard method for detecting it. Originally all affected persons were thought to be blond and blue-eyed and to have a very low intelligence, but further experience has shown that some patients merely have less pigmentation than other members of their family and that in some races pigmentation may be normal. It has also been shown that the scatter of intelligence in the untreated state is considerable, a few patients being well within the normal range.

The basic defect in phenylketonuria is the absence of the hepatic enzyme, phenylalanine hydroxylase, which normally converts into tyrosine the dietary phenylalanine which is not used up in the synthesis of protein. In the absence of this hydroxylase phenylalanine accumulates in large amounts in the blood and is partly converted, by alternative metabolic pathways, to phenylpyruvic acid and other metabolites, which are excreted in the urine. Unchanged phenylalanine is also present in the urine.

Phenylketonuria is inherited as an autosomal recessive; the heterozygous parents of affected children are therefore clinically normal, nor does their urine contain phenylpyruvic acid. The heterozygous state can, however, be detected by phenylalanine loading tests. When a child with phenylketonuria is born there is statistically a 25% chance of a similarly affected sib being born to the same parents.

The relationship between this metabolic error and mental subnormality is largely derived from observations on man. Nearly all persons with phenylketonuria have a very low intelligence, but giving a diet low in phenylalanine to affected infants from an early age will usually result in a child of normal or nearly normal intelligence. At page 133 of the *B.M.J.* this week Dr. Barbara Clayton and her colleagues in London describe their experience in the treatment of 57 children with phenylketonuria. They have shown that early diagnosis, with careful dietary and biochemical control, produces excellent results. Eleven children in their series attend a normal school, and 10 children of pre-school age will also be eligible for normal schooling if their present level of intelligence is maintained. In those children in whom the diagnosis was made and treatment started before the age of 6 months the intelligence quotient before treatment was normal, and the effect of treatment was to maintain it at a normal level. In the majority of those in whom treatment was started after the age of 6 months the intelligence before treatment was well below normal, and even with prolonged treatment it was rarely possible to achieve an I.Q. of 80, though substantial improvement was made in just under half of these children.

Several important conclusions can be drawn from this work, which is representative of that done in many other paediatric centres. For an affected child to have normal intelligence the treatment must be started as early as possible, certainly before the age of 6 months. Dietary control is essential and must be combined with repeated estimations of the level of serum phenylalanine as the presence or absence of phenylpyruvic acid in the urine does not afford a sufficiently sensitive test. Some improvement in intelligence and behaviour may result from the dietary treatment of older patients, and another reason why they should be sought is that the discovery of an older child with phenylketonuria will alert the paediatrician to the possibility of similarly affected sibs, born and unborn. An important observation about the adult with phenylketonuria is that when an affected woman becomes pregnant and is not treated by diet during the pregnancy the infant will probably be mentally subnormal, though not suffering from phenylketonuria. This is due to the influence of a raised maternal, and hence foetal, level of phenylalanine on the developing brain. Fortunately the converse of this situation is more commonly seen: the affected infant is normal at birth because the placenta is able to maintain the foetal level of phenylalanine within normal limits.

The best way of ensuring early diagnosis and treatment is by routine screening tests on all young infants. The present method in general use is to test the urine, or more commonly the napkin wet from freshly voided urine, by means of the Phenistix test paper (a modification of the ferric chloride test). This test is not reliable immediately after birth and is usually performed at the age of 3 to 6 weeks. In practice the results of widespread use of this test have been disappointing. Dr. Clayton and her colleagues found that only ten of their series were detected at infant welfare centres, and of these only two were under the age of 6 weeks. A more satisfactory procedure, the Guthrie test,[2] is done on a drop of blood dried on filter paper, which is then sent to a central laboratory. This test can be done as early as the fourth day of life, provided the infant is feeding well and has therefore a normal intake of protein. Suspected cases detected in this way are then investigated by more precise methods. Even so, difficulties may arise in the interpretation of a raised level of phenylalanine, as it has been shown that in some premature infants the serum phenylalanine may be temporarily raised,[3] often with a positive Phenistix test. This is thought to be due to delay in the maturation of the enzyme systems dealing with phenylalanine and tyrosine. Such infants can on further investigation be distinguished from true phenylketonurics, and should of course never be treated as if they had this condition.

Perhaps the most difficult decision, once treatment has started, is when to stop. F. P. Hudson[4] has described four children who returned to a normal diet after treatment for 2½ to 5 years. Observation of them on a normal diet for varying periods has as yet disclosed no deterioration. Dr. Clayton and her group are as yet reluctant to commit themselves on this point.

The incidence of phenylketonuria in a population of northern European origin is probably about 1 in 10,000 births, but the condition appears to be less common in American negroes and in Ashkenazi Jews.[5] It has been described in Japan and recently in North American Indians.[6] The rate of early detection in Britain could be greatly improved. To make the diagnosis only when mental subnormality is suspected is to make it too late.

Bristol A.R.M.

With the longest agenda in its history the Representative Meeting in Bristol was always in danger of becoming submerged under the mass of business. It did not altogether escape this fate. Although extra time was taken and representatives exercised considerable self-denial, the end was reached only by disposing of many items on the last day without discussion. The Meeting recorded its regret at the shortness of time available for hospital affairs. However, despite all the difficulties the Representative Body dispatched a useful amount of business during its four-days sitting.

A motion from Birmingham urging a delay in legislation on therapeutic abortion until an independent tribunal, such as a Royal Commission, "had collected, scrutinized, and reported" on all the relevant facts was taken early, because of the imminent passage of Mr. Steel's Bill through the House of Commons. The Representative Body had to decide whether to lend the Association's weight to those who wanted the present Bill to fail, or whether it should recognize that Mr. Steel's Bill was, as one speaker said, "probably the best Bill [we shall] ever get." It was one to which the Association together with the Royal College of Obstetricians and Gynaecologists had already contributed much. The Bill now makes the decision to terminate a pregnancy entirely a medical matter, depending on assessment of the risk to life and health of the woman and her existing children or of serious foetal deformity. This is a long way from the purely social indications the Bill once contained. After a lively debate and hearing that the B.M.A. would continue to press vigorously for certain important amendments to the Bill, the Meeting rejected the Birmingham motion by 274 to 98 votes.

One or another aspect of the Health Service formed the subject of a number of motions. Among many of minor importance some that dealt with matters of principle stood out. Asked to revoke the 1945 S.R.M.'s undertaking that the profession would, with certain provisos, accept a health service that was available to the whole population (the "100% issue") the Meeting instead recorded its view "that the profession can no longer accept collective responsibility for the preservation of a standard of medical care which a modern community should expect under the Health Service." This is a warning which the public and the Minister should heed. The tenancy arrangements for doctors working in local authority health centres were seen as a possible threat to the independence of general practitioners. Official interest in building such centres is increasing. Indignation that the patient's signature as well as the doctor's should be required on the form for payment for itemized services such as night visits was voiced. Did a doctor's signature no longer command trust, it was asked.

After an undertaking that the Council would examine alternative proposals from the East Yorkshire Branch and after a thorough discussion, the new constitution emerged from its ordeal by debate amended but recognizable. Proportional representation is to be introduced, but a Division's right to individual representation in the R.B. was successfully championed. Each of the 21 hospital regions will elect to the R.B. a representative of its junior hospital staff. Its future size will be about 538. By its provisions for dealing with the work of the autonomous committees the new constitution should do much to relieve Representative Meetings of the burden of the sort of trivialities which contributed so much to the unmanageable size of this year's agenda. The R.B. will retain its sovereignty, as it must, and be free to consider the report of any committee, but it will normally address itself only to questions of major policy. Perhaps more than any other measure, this will enhance the usefulness of the Association's Annual Representative Meeting, and therefore its prestige.

The Meeting, which was ably chaired by Dr. A. N. Mathias, is reported in the *Supplement* at p. 25.

Chemical Treatment of Skin Cancer

In contrast with other forms of neoplasia, skin cancer is relatively easy to treat. Diagnosis can be made early, the full extent of the lesion can be ascertained readily, complete extirpation by surgery or ionizing radiation is usually possible, and the effects of therapy can be evaluated without difficulty. In the case of basal-cell tumours the fact that distant metastasis is rare also favours a good prognosis, and cure rates of 95% or better can regularly be obtained by the traditional methods of treatment.[1 2] Is there therefore any place for chemotherapy in the treatment of skin cancer ?

In the treatment of internal cancer by chemotherapy the problem is to find chemical substances more toxic to cancer cells than to normal cells. Most of the success of the chemotherapeutic drugs now in use depends on their selective toxicity for proliferating cells. The same property limits their use, because they damage not only proliferating tumour cells but also proliferating normal cells, particularly those of the gut mucosa and blood-forming tissues. Recently attempts have been made to concentrate the effect of chemotherapeutic agents on tumour cells by perfusion or local intra-arterial infusion. Attempts are also being made to develop rapidly destroyed cytotoxic drugs for administration by infusion, the intention being that by the time they have passed through the tumour and into the general circulation their cytotoxicity will have been lost.[3] Yet another approach is to develop cytotoxic drugs which are linked to other molecules—for example, tumour-specific antibodies—which can be expected to "home" on the tumour cells.[4]

In the treatment of skin cancers there is no need to use chemicals with selective toxicity, because agents can be accurately and directly applied to the cancerous tissue, and, provided absorption into the body is limited, exposure of normal tissues can be reduced to a minimum. It is not surprising, therefore, that many relatively simple chemical substances such as sodium bicarbonate[5] and zinc chloride[6] have been shown to be effective in eradicating skin cancers. More elaborate toxins such as colchicine, demecolcine, *N*-desacetylthiocolchicine,[7] and podophyllin[8] have likewise been found effective.

According to E. Klein and his colleagues,[9] 5-fluorouracil, an agent developed specifically for the treatment of cancer, is not suitable for the treatment of basal-cell carcinomas, let alone squamous carcinomas. J. C. Belisario,[7] on the other hand, suggests that agents such as methotrexate and triaziquone, alone or in combination with colchicine or colchicine-like agents, have an important place in the treatment of skin cancer in Australia, where the disease is common.

In general it would seem best to continue to use the well-tried methods of treatment—namely, surgery and radiotherapy—particularly where special considerations discussed by Belisario[7] for using chemotherapy do not apply. But are we failing to make proper use in selected cases of the technique of chemosurgery developed by F. E. Mohs[6] ? In countries other than Britain it has proved to be of considerable value in the treatment of flat, sclerotic basal-cell carcinomas with poorly defined margins, of tumours near important anatomical structures such as the nasal ala or orbital canthus, and of tumours that have recurred after surgical removal or radiotherapy. The special value of the method lies not in the fact that extirpation is accomplished by chemical means (zinc chloride) but in that it is controlled stage by stage by the systematic microscopical examination of tissues removed from the base of the lesion, so that complete removal is achieved with the minimal destruction of normal tissues. Mohs claimed a 95% five-year cure rate for previously treated basal-cell carcinomas and a 99% five-year cure rate for previously untreated lesions. Other surgeons have reported comparably good results.[10-17] N. L. Morgenstern and R. W. Leeper[18] also confirmed the value of chemosurgery and provided a useful brief description of the method and indications for its use. They do not recommend chemosurgery for the small uncomplicated lesion, because the application of zinc chloride may produce severe pain (controllable by analgesics) and oedema. Moreover, the technique is more time-consuming for both the patient and his doctor. However, for the appropriate case these authors[18] regard chemosurgery, which can be performed by any pathologist and dermatologist working as a team, as the method of choice.

It is difficult to believe that any form of local treat
whether by chemical agents or electrodissection
curettage,[19 20] can be as successful in the treatment o
cancer as Mohs's technique unless it includes the same s
of careful histopathological control. Herein lies the rat
for using zinc chloride, since it acts sufficiently well
fixative to permit a flat layer of tissue removed from th
of an ulcer to be examined systematically for the prese
tumour tissue. Precise evaluation of this kind is not p
in treatment with other types of chemical agent
curettage.

In the main, therefore, surgery and radiotherapy r
the best methods for treating skin cancer, though ther
need to introduce the technique of chemosurgery into B
The use of no other form of chemical treatment is just
unless it involves stage-by-stage histopathological evalu
the essential feature of Mohs's technique.

Needs of Pre-school Children

The National Society of Children's Nurseries has re
published a report by Dr. Simon Yudkin of an inqu
a working party which met under his chairmanship t
into the care, outside their homes, of children under
age.[1] The working party of 18 members represent
principal professions closely concerned with the w
health, and education of pre-school children. In her for
Lady Allen of Hurtwood bluntly asserts that the aim
report is "to stir into action the Government, Memb
Parliament, local authorities, and the general public"
regard to what she characterizes as the "chaotic terri
of existing provisions for nursery care and education.
society is supported in its demands for a Government i
by 33 voluntary and professional organizations interes
the social welfare of mothers and children under 5 ye
whom there are more than 4¾ million in the country.
Yudkin marshals considerable evidence to support hi
tention that, "although provision for their physical ca
stand comparison with those of any country, and the
detection and management of handicapped children is in
ing year by year, by contrast, provisions for their soci
emotional development and training are chaotic, inade
and based on no apparent general philosophy."

The report is in three parts. The first section ex
the position of working mothers and reviews the ne
their young children in two main age groups, since t
general agreement that the needs and tolerances of ch
aged up to 3 years and of those aged 3 to 5 differ in
respects. There are also wide variations within these
according to family unity, domestic arrangements, ho
economic circumstances, and, in some cases, physi
mental handicap. The second section, dealing with
minding and with day and residential nurseries, pr
disquieting evidence of the exceedingly unsatisfactory an
dangerous conditions under which many young child
this country are illegally looked after or fostered. The
section offers comment and suggestions. Though o
facts and figures are not available, much useful inform
has been painstakingly collected from various agencie
published reports, which is supplied in the appendix.

---

[1] Yudkin, S., *A Report on the Care of Pre-School Children.* N
Society of Children's Nurseries, 45 Russell Square, London
5s. net.

After 1945 Ministerial policy was directed—and it is only fair to remember, in the conditions then prevailing or expected, with every good intention so directed—towards the closure of wartime day nurseries and the encouragement of family care of young children. At the same time shortage of teachers necessitated a limitation of nursery schools and classes. But social conditions have greatly altered since then. The age of marriage has fallen and the birth rate has risen. The cost of living has soared. The number of mothers, particularly young mothers at work, has increased rather than diminished. The housing situation remains difficult. There has been an influx of coloured immigrants with low earning capacity and large families, and these have tended to congregate in already overcrowded industrial cities such as London, Liverpool, and Birmingham. Though previous lack of foresight in high places may be regrettable, past miscalculation is no excuse for present inaction. The miseries and dangers which unknown numbers of helpless babies and young children are at present enduring in our midst cannot be ignored. The situation calls for urgent investigation and vigorous remedial measures.

While there can be no possible disagreement with the main thesis of this report, for which the National Society of Children's Nurseries is to be commended, there is one serious omission which will immediately strike workers interested in developmental and social paediatrics. There is no mention of one of the most needy of all groups, the children aged under 5 in hospitals for the mentally subnormal, a group which for some inexplicable reason was also omitted from the terms of reference of the Platt Committee on the Welfare of Children in Hospital. Any new inquiry must not be allowed to perpetuate unjustifiable hierarchical distinctions between physically, mentally, emotionally, and socially handicapped children. The quantity and quality of provisions for the care and welfare of all children under 5 years who are cared for outside their own homes should be investigated and remedied where necessary without exception. It is to be hoped that urgently needed legislation will be promptly considered, clearly defined, and thereafter strictly enforced.

Safety of Drugs

The Committee on Safety of Drugs has two main functions. It requires manufacturers of new drugs to submit evidence to establish that it is reasonably safe to start clinical trials, and later requires further evidence on safety and efficacy before the drug is released for marketing ; and it collects and assesses information about adverse effects of drugs in general use. The committee's third annual report,[1] published this week, shows that both functions are working smoothly.

In 1966 there was a small rise in the number of submissions on new drugs (908) made to the committee, which claims that delay in clearing the drug has been kept to a minimum by the use of informal discussions rather than official communications. The committee's policy is that only in the most exceptional circumstances will it release any drug for clinical trial in women of child-bearing age until tests for teratogenicity have been carried out in animals, and the report points out that this policy has led in some cases to populations used in clinical trials being unbalanced. Manufacturers are advised to carry out tests for teratogenicity early in the programme of assessment.

In the three years during which the " early warning system " for reporting adverse reactions to drugs has been in operation twice as many reports of suspected adverse reactions to drugs have been received from general practitioners as from hospital staff. The committee suggests that this may be due to some confusion in the minds of doctors about the nature or severity of reactions that should be reported. The report states:

> " Broadly, doctors and dentists are asked to report all suspected reactions, however trivial they may appear to be, following the administration of drugs introduced on to the market within the past two years: they are asked to report all serious or unusual reactions to drugs which have been on the market for a longer period. When there is doubt about the date of marketing, the doctor or dentist should always report his observations."

The committee proposes to issue more reports in the Adverse Reactions series, and in the case of widely prescribed drugs it will provide on request " extract sheets " summarizing the cumulative reports received on them.

Finally, the report draws attention to the narrow limits within which the committee is concerned with the efficacy of drugs. Clearance of a drug by the committee does not necessarily imply that it thinks the drug is a valuable remedy, but only that it is safe for the purpose for which it is intended to be used. " Thus, a number of products which in the committee's view are relatively worthless, though innocuous, have been cleared for the market."

Bed Rest and Lumbar Disc Protrusions

The results of surgical treatment of protrusions of lumbar intervertebral discs have been well documented. J. E. A. O'Connell[1] reported on his results in 500 patients all of whom had severe or prolonged symptoms before operation. In his follow-up he found that 92% were either completely free of pain or very greatly improved after operation and that recurrence of symptoms severe enough to indicate reoperation was 2%.

The great majority of patients with symptoms due to this condition are treated by conservative measures, but there is surprisingly little factual information on the long-term results. J. Pearce and J. M. H. Moll[2] have recently corrected this in a study of 91 consecutive patients with acute symptoms considered to be due to a lumbar disc lesion, the patients being admitted in the course of 13 years. In all patients there was restriction of spinal flexion and of straight-leg raising and in the majority signs of nerve-root compression. The authors omitted from the series patients with a strong neurotic element and those in which there was any diagnostic doubt. Unfortunately they also omitted patients who were submitted to early operation on account of intractable pain after one to two months of absolute bed rest and those with evidence of compression of the cauda equina and sphincter disturbance. It would be of value to know how many patients come into this category. Treatment was strict bed rest with a fracture board under the mattress and one pillow. If the patient was free of pain after two weeks he was gradually mobilized, while if pain persisted he had a further fortnight's bed rest. When walking was possible without pain he was discharged and returned to work within a few weeks, and he was advised not to bend or lift heavy objects for three months.

---

[1] *Annual Report of the Committee on Safety of Drugs,* 1967. H.M.S.O., London.

[1] O'Connell, J. E. A., *J. Bone J. Surg.*, 1951, 33B, 8.

[2] Pearce, J., and Moll, J. M. H., *J. Neurol. Neurosurg. Psychiat.*, 1967, 30, 13.

The series included 38 patients in their first attack of pain and 53 who had had previous attacks. The follow-up was an average of eight years (range 0–13), but 18 patients could not be traced. Five patients (7%) had developed severe recurrence of symptoms and had been operated on. Of the remaining 68 patients 26% remained completely free of pain, 41% had persisting mild pain, and 32% were still complaining of moderate or severe pain. The authors also analysed the 68 patients' ability to work since the original hospital admission: 57% had not lost time off work, while 43% had had recurrences sufficiently severe for them to have periods off work, some of them for two months or more at a time; 71% were still doing their original type of work but 29% had had to change to lighter work.

It is sometimes thought that if a patient recovers from the acute symptoms of a lumbar disc protrusion with a period of bed rest he is likely to remain free of serious disability, but this valuable study shows that this is not so in more than 30% of the patients. The question arises whether persistence with spinal-extension exercises after recovery from the acute attack might help to prevent recurrent pain. The authors' findings certainly suggest that, when there are repeated episodes of pain sufficiently severe to stop the patient from working, operation needs serious consideration.

Tinea in Hospitals

One of the hazards of community life is the risk of acquiring tinea pedis, and this is well recognized in schools, the armed Forces, coal mines, and elsewhere. Now Dr. Mary English and her colleagues at Bristol report in the *B.M.J.* this week (page 136) their investigations on mentally subnormal patients in a long-stay hospital. The patients lived in numerous separate "lodges," between which there was only a limited interchange. Scrapings were taken from all suggestive lesions on hands and feet, and types of fungus were identified by culture. About 40% of those examined gave positive cultures. Among these *Trichophyton interdigitale* was the commonest (50%) and *T. rubrum* the next (26%), with *Epidermophyton floccosum* a poor third (4%). The incidence of infection was related to the length of the patients' stay in hospital but not to their ages. In the lodge containing the longest-stay patients the incidence rose to 66%, which approximates to that found in coal mines in England[1] and Germany.[2] The authors suggest that the residual 30–40% may represent the proportion of the normal population who have a natural resistance to the infection. The frequency of *T. interdigitale* infections was about the same in each lodge, but in one lodge *T. rubrum* showed a significantly higher incidence both absolutely and in relation to *T. interdigitale* and it caused more severe lesions. A possible explanation of these findings is that, while there was multiple introduction of *T. interdigitale,* the outbreak of *T. rubrum* may have resulted originally from a single case. This is comparable with the findings of J. C. Gentles and J. G. Holmes[1] in coal miners; in some pits there were hardly any cases of *T. rubrum,* while in others its incidence was over 40%. *T. rubrum* was comparatively rare before 1939, but since then it has become increasingly common, and once introduced into a community it may spread rapidly. It was originally one of the most intractable forms of ringworm, but now fortunately can be controlled by griseofulvin. Gentles and Holmes showed that there was an association between the spread of tinea pedis and the use of pit-head baths, but Dr. English and her collaborators could find no relationship between their patients' use of the bathroom and the spread of the infection. On the other hand they were able to culture fungus from socks which had been laundered, a fact of importance because the socks were not the property of individual patients but were reissued indiscriminately after laundering. Furthermore, four out of nine crippled patients who had never walked had ringworm, so that the authors considered that infected socks were probably a more important source of infection in this community than contaminated floors. Football trousers worn indiscriminately after laundering have been known to spread tinea cruris likewise.

How far are these findings relevant to hospital conditions generally? It seems unlikely that there would be much interchange of socks and underlinen between patients in an ordinary acute hospital except possibly for pyjamas. Tinea cruris is less common than tinea pedis, and it must be rare for the former to be contracted in hospital from pyjamas. However, tinea cruris has been spread by contaminated towels used in a physiotherapy department. It seems probable that the chief risk in acute hospitals is in the bathrooms, though whether the risk warrants active preventive measures, such as the provision of disposable slippers, is doubtful. On the other hand, in communities of long-term patients it would seem a simple and reasonable precaution to ensure that each patient should have his own socks returned to him from the laundry. It is debatable how much further one should go in improving preventive measures and the restrictions they necessitate, particularly in a community of patients with a low mentality who frequently walk about barefoot in the dormitories as well as the bathrooms. In this relatively cold country tinea pedis is rarely a disabling disease.

But eastward, look, the land is bright

Following a practice that has already been found fruitful in other fields, the Ministry of Health is to send a team over to the U.S.A. and Canada next October in the hope of persuading medical emigrants to return to practise in Great Britain. An announcement giving the details appears in the advertisement on the inside front cover this week. Among those who have emigrated are many young men and women who could make an outstanding contribution to medicine in the country of their birth. The great majority of them on qualifying had no thought of making their life's work anywhere but in Britain. Why then did they go? This question has evoked a multitude of different answers, but essentially most emigrants are dissatisfied with either the postgraduate training or the professional prospects offered in this country, sometimes with both. If the Ministry team can convince them that real improvement is on the way it may succeed in persuading at least some of these doctors to turn their steps homeward.

Papers and Originals

British Medical Association

ONE HUNDRED AND THIRTY-FIFTH ANNUAL MEETING, BRISTOL, 1967

President's Address

One Profession, One Purpose

ROBERT V. COOKE,* CH.M., F.R.C.S.

Our beloved Queen, in her most recent Christmas message, spoke of concern for others—in fact this matter of being concerned ran through all that broadcast, in which she paid so many tributes to womankind, generous, but how true. She particularly praised them for their sagacity, tenacity, and loyalty, attributes which we would all wish to possess.

About this time I attended my first B.M.A. Council Meeting. What struck me most was the evident concern of all those present for the plight of two of the smaller groups of our profession. With a long agenda there was no hurry; the most careful consideration was given to the problems besetting these colleagues, in some ways less fortunate than others and standing in need of help.

My attendance at all subsequent Council Meetings has convinced me that that first impression of their concern for minority groups was no mere chance. Since then there has been anxiety and concern for the present position and future of senior hospital medical officers and senior administrative medical officers, Service doctors, and whole-time teachers. On the last occasion there was a prolonged and most sympathetic hearing of the special case of public health doctors. It was the main preoccupation of the meeting, and I have been most impressed. Impressed, too, with the support given to the more junior doctors, who have now achieved substantial representation on important committees, and are playing an active part in negotiations at a time when their needs are great and urgent.

For many months I had been casting about for a subject for this special audience—not too technical and not too inflammatory. At one time I was almost tempted to repeat that memorable address at Oxford four years ago—as brief as it was memorable. Then, as you remember, Sir George Pickering said that he had "felt like a Sunday preacher seeking for a text," which he found in the mottoes of Winchester and New Colleges—"Manners Makyth Man." His captive audience will remember the account he gave of William Wickham, and the theme which followed—"The ethos of medicine is of no less significance than the science" and "that this must not be squandered." "It was manners that makyth man—that character and conduct mattered at least as much as learning," though, of course, we must have both. He spoke of arrogance, selfishness, and alcohol as examples of bad manners and the cause of much injury and grief, particularly in regard to road accidents. This was evidence of lack of concern for others.

So it was that I came to my text or title—based upon concern for each other and concern with the service we give—"One profession, One purpose."

Unity

We hear a great deal about the importance of the unity of peoples, of countries, of the Churches. This oneness is surely imperative for our great profession, and never was it more needed than now. Each of us must have real concern for the whole profession, every branch, every group, however small. It has gladdened the heart to have seen this spirit in operation in your Council and on your Committees. We might with advantage remind ourselves of our own good fortune, of all the help we have received because others have been concerned about us. Maybe it was a parent, a schoolmaster, a particular friend in the profession, or a wife whose concern for us and for others has meant for her a life of selflessness, perhaps taken too much for granted. It may even have been the British Medical Association.

Sir Ian Fraser, in his Belfast address, deplored "this disintegration from which the consultant side of the profession must be saved," referring particularly to divisions into teachers, clinicians, and research workers. After all, the so-called clinicians must be responsible for a great deal of the teaching, and who better able to do so? The clinicians should encourage the researcher and the laboratory man, dependent as they are on their special labours. They should not only receive their meed of praise, but we must see to it that they are properly paid and efficiently equipped. But of greater importance is the development of closer bonds of unity between the family doctor and all the rest of the profession.

William Stokes, Regius Professor of Physic at Dublin, and President of the B.M.A. 1867–8, in his valedictory address at Oxford, said: "So far we have been an united body, working for the benefit of science in the world, with independent local action and a representative on the central executive. How long this strength-giving union may last no man can predict, nor on the other hand can any man say to what amount of influence for good this association may attain.

"But it is plain that its durability and usefulness will depend on its being made the instrument for public good rather than the machinery to advance the immediate worldly interests of the profession."

I could mention many examples showing how in recent months concern for others in our profession has led to active steps being taken and not just pious hopes expressed.

The changes proposed in the composition of the Central Consultants Committee of the special Negotiating Committee of fifteen, which will replace the present one of nine members, were all designed to give the younger men an important say in our deliberations, and not only as regards terms and conditions of service. The committee on training at the Royal College of Surgeons will now from time to time invite representatives of those younger men in training to listen in, as it were, and express their own views on any plans envisaged for their future education and examinations. We look for happy co-operation, not a grudging acceptance of regulations laid down. After all, the younger men are not so young. Anyone attending the last Junior Doctors Forum in Manchester or that special meeting in Newcastle would have satisfied themselves that many are mature, thinking people, capable of adding strength to our discussions, and bargaining with the administration. By integrating these younger men and women into our councils we are at once strengthening and unifying our Association.

---

* Senior Surgeon, Bristol Royal Hospital.

The National Health Service will not make people healthier. But it is a part of our national way of life. It must be made to work. And, as regards the saving of expense, it is my personal view that we are not doing all we could and should to preserve this Service, for it must be preserved. The astronomical expense could be cut. We may not be able to tackle the administrative costs, but we should do whatever we can; for a little here, with a little there, can add up to a considerable sum. It is so easy to be complacent or to feel that our little efforts are of small account. In any case, inevitably we must need more and more to meet all kinds of new expenditure as science advances and many new and expensive procedures are developed. Kidney transplants are now almost commonplace, and other organ transplantations are in the offing. Haemodialysis presents ethical and moral problems, but certainly the cost is going to be great.

The Cost of Life

The recent symposium at the Royal Society of Medicine (under the able chairmanship of Lord Cohen) served to emphasize the price we must pay for these refinements of treatment. Yet we *must* concern ourselves with the tetraplegic, the mongol, the hydrocephalic, the spina bifida, and the serious head injury in particular. To listen to these papers made one realize something of the future developments and demands. The horizons of medicine are limitless and none can foretell how far we may be able to go. But there can be only one standard of treatment. We cannot choose a treatment for one and give something less to another. We may not play God, —we must accept the risks involved and constantly try to improve our results.

As doctors we should never too readily give a certificate of unfitness or for minor ailments. Men and women taken out of industry and kept out of work are paid for doing nothing. Demoralizing for them, it is bad for the country. Convalescence, be it from medical disease or surgical operation, is often so protracted that it has itself to be recovered from. Between us, doctor and consultant together, we must try harder to get patients back to work just as soon as is reasonable. In many conditions the early return to useful activity makes the best possible contribution to full mental and physical recovery.

Governments, at their wit's end to find more and more money, might more readily be persuaded to look again at the Health Service if it was seen that all of us were contributing something in one way or another to eliminate wastage. Many have given much thought to methods of collecting money from other sources, but some such measures suggested might provide a relatively small return for a big outlay in money and manpower. It is said that, unlike other activities, we have no end-product for sale or for export. Surely we have the best of all—positive health. Our great trade unions know this and are alive to the fact that illness and absenteeism account for more loss in working days than all the strikes put together. One cannot at this moment refrain from saying a word against overemployment if only because of its bad effect on real health of mind and body of those insufficiently employed. Standing about on the shop floor is much worse for them than a certain degree of overwork.

Use of Hospital Beds

Another contribution concerns the more careful use of hospital beds, for there is no doubt that bed-stay in various parts of the country varies between wide limits. We should save every single day that is reasonably possible, having regard to the home conditions of the patients about to be discharged. Serving on a regional board I saw something of the work of the geriatrician. Some of them contrived to save the use of hospital beds in a remarkable way—a real contribution, saving money and personnel to be deployed to meet other demands.

Sir George Godber said in Londonderry that the fullest possible use should be made of outpatient departments. With complete collaboration between the family doctor and the consultant, Farquharson, of Edinburgh, has shown what can be done in this respect with regard to operations for hernia, and we are all well aware of Fegan's admirable work in Dublin, where he has re-emphasized and improved the injection treatment of cases of varicose veins as outpatients.

I am glad that for my first fifteen years as a consultant I served in a voluntary hospital, and, brought up in that old school, I have never felt it was right to have a waiting-list for outpatients, or at most a very short one. Though I am prepared to admit that in some specialties it would be difficult to follow this practice, I would just like to say that by using the help of a senior registrar, a senior house-officer, and a house-surgeon we ran an outpatient service with no waiting-list. Sometimes we were in a little trouble with the establishment, overstaying our allotted time, but the service we give to patients in need is all-important. We were saving money, too, because patients waiting for a consultation were only too often put off work in the meantime. The cost of drugs was constantly under review by a watchful subcommittee who found that at the Bristol Royal Infirmary there were wide variations in the use of drugs without noticeable difference in results. I was proud that I was about the cheapest consultant available. Obviously there must be special allowances made for research.

Emigration

A further aspect of the Health Service is the vexed question of emigration, for beyond certain limits this burden may be too heavy to bear. For many years now medical students have received free or greatly assisted education and training by funds ultimately raised from the taxpayer. The Minister was surely right when he pointed out that there was a moral obligation to give something in return to the country. In Egypt there is an enforced period of service wherever there is need, and the scheme works well. There is no doubt that certain countries, badly needing doctors in all but their larger towns, are proudly exporting far too many of their own well-trained young men and women.

The loan method is not a new idea, but the soaring costs of higher education may force the introduction of this alternative in the place of direct public grants. The loans would have to be repaid over a period of years after qualification, when students have started work. Professor Vaizey put the case clearly before an audience at Sussex University as recently as last month.

Now that continuing education in our hospitals is receiving more attention, house-officers are not just regarded as hard-working pairs of hands. Their interests, their futures, are being cared for by special lectures and demonstrations, so that they are more prepared for whatever step they next propose to take. This was one of the things, among many, that we learned from our friends across the Atlantic, and until recently the absence of such concern was one of the causes of emigration and the loss of promising young men from our country.

And thinking of continuing medical education, I feel I must speak for the cottage hospital, which, properly used, is still a means of continuing medical education, both of visiting consultants and of the local family doctors who bring their cases for discussion. Both learn; the consultant learns again to appreciate the doctor's difficulties, and, though expensive in consultant time and labour, this should be shouldered in the interest of service given on the spot, with the saving of patient's time travelling to and fro, perhaps many miles each way. The local community hospital is still a valuable and viable entry. It is up to us, particularly the consultants, to use these lively useful hospitals wisely and well. They will then never disappear.

Purpose

Nothing is better calculated to preserve the unity of our profession than a purpose, a creed, almost a religion if you like. Purposes may be partly or wholly evil; but powerful, even fanatical movements have often solely depended on a unifying sense of purpose.

When we come to reflect on our service to our patients may I refer you again to the Oxford address: "Yet they get stupefied with drugs or afflicted with unnecessary surgery." I would add—tormented by innumerable, tiresome, and often unnecessary investigations, which can be painful, even frankly dangerous, quite apart from the cost to the service in manpower and bed usage, with the inevitable delay imposed on others.

Clinical Diagnosis

To my mind this is largely due to a gradual loss of the science and art of clinical diagnosis. Here is the root cause of the abuse of all these ancillary investigations. Consultants must accept their fair share of blame. With so many laboratory facilities and all manner of superb radiological aids at hand they too readily resort to these and more elaborate methods before they have tried to get as near to the truth as possible without them. Thus the taking of infinite pains with the history, and exquisitely careful and complete examination of the patient, is so seldom seen that when it is it is a cause for special notice instead of being the rule and sheet anchor of diagnostic procedure. I am sure we should reaffirm our faith in clinical diagnosis, teach it more carefully, recognize that it takes a long time to learn, requiring as it does a great deal of experience, quite apart from a vast amount of knowledge, correctly to interpret the story and the physical findings. By emphasizing the importance of these time-honoured methods we are encouraging our family doctors in their work, for of necessity they will always have to rely largely on their powers of clinical diagnosis, even though many of them may have access to pathological and radiological services. The first suspicions of disease must always be their responsibility and concern, even if selective investigations are found necessary either to support a clinical suspicion or to provide a more complete or more precise assessment of the case.

Yet the teaching of diagnosis is not enough. The clinical teacher must all the time be doing his best to explain the scientific method in addition to his efforts to train powers of observation, and thought. In his fine Harveian address in 1963 Dr. Rae Gilchrist used again the words of Bacon: ". . . the desire to seek, the patience to doubt, the fondness to meditate, the slowness to assert, the readiness to reconsider, the carefulness to dispose and set in order; . . . and to hate every kind of imposture." And he went on to say that "One result is that sound judgement can often dispense with multiple diagnostic tests and the battery of biochemical analysis which masquerade as the scientific approach in current hospital practice. The limitations of the scientist tend to be revealed when discrimination, judgement, and wisdom are in short supply."

We must never forget a mistake—we must ponder over it, learn from it; and I mean mistakes of omission as well as those of commission.

In all our efforts toward the education of future consultants or family doctors we must see to it that they are firmly determined to practise the art and science of clinical diagnosis, and encourage this rather than direct their attention to all the tests which are possible and which on occasion may be necessary. This is particularly true for those of us who frequent other less-advanced countries, who need encouragement, and who must not be exasperated by extolling investigations which in the main are beyond their present resources.

Clinical Judgement

But clinical diagnosis of a high order requires a special capacity for judgement, the ability to set aside the unimportant, the irrelevant, and seize upon the important facets of the problem case. In the Usher Hall in Edinburgh, where many medical conferences are held, there is a dome-shaped ceiling—very high up, unhappily not so well seen by the audience, but there for all speakers to read, if they care to look, are the well-known words: "Wisdom is the principal thing, therefore get wisdom, and with all thy getting get understanding."

This kind of wisdom and judgement is attained to only by long years of application, and, with some, never at all. But it is something beyond price and, for those who acquire it, the hallmark of a great doctor, whatever branch of medicine he adorns.

Of course there are limits beyond which clinical diagnosis cannot go, but even then many possibilities should have been ruled out and consequently investigation reduced to a prudent minimum. It is necessary, too, to remember that results from investigations may mislead, giving rise to a false sense of security. It is well to be particularly sceptical when such results conflict with a considered clinical assessment, or even a well-based clinical impression.

It happens that in three of my own special fields of interest—the thyroid, the biliary tract, and the large bowel—the painstaking history coupled with a most careful and complete physical examination more often than not will enable the physician or surgeon to make a confident diagnosis, or at least be able to decide on the wisdom of an exploration without any recourse to special tests.

I must not weary you with example after example to illustrate my point. Suffice it to say that the acute abdomen, the injured abdomen, as well as those many cases where the abdomen can be wrongly incriminated—the actual cause of symptoms being derived from an extra-abdominal cause—these all almost entirely depend for their successful management on sound and maybe rapid clinical judgement, based on clinical diagnosis or reasoned clinical suspicion.

All this of course takes time, but the more the family doctor can do the fewer should be his calls on the hospital service. The doctor will need adequate time to do this efficiently, but if he is not burdened with too many patients he will give the kind of service which will automatically cut down hospital work and outpatient waiting-lists. If, added to this, the consultants relied a little more on clinical diagnosis and a little less on multitudinous tests much labour and expense would be saved. I am sure it is our bounden duty in this and every possible way to have regard to the expense of this National Health Service of ours.

All too often the surgeon or physician is thanked and praised for his promptitude and skill; but maybe it is the family doctor who should get the praise and gratitude, for it was he whose suspicion was first aroused, and the consultant called in may have a relatively easy problem on his hands. A timely operation or a prompt removal to an intensive care unit has been entirely due to his informed mind, his wise judgement. Let us give, and make a point of giving, praise when and where praise is due . . . . One profession—one purpose.

Iatrogenics

Concern for our patients' good must inevitably lead to the study of iatrogenics—that is, the study of disease and disability inflicted or created by doctors.

Our Gold Medallist today in 1965 said: "No remedial agent or measure is without its hazard. Yet to be over-cautious may result in lack of performance." The same caution should be observed if risk of iatrogenic disease is to be avoided when using certain methods of investigation.

Hippocrates, 460–335 B.C., said: "First do no harm."

Bonaparte, 1820, said: "I do not want two diseases, one nature-made, one doctor-made."

Osler, 1894: "But know also that man has an inborn craving for medicine . . . which distinguished him from his fellow animal creatures. It is really one of the most serious difficulties with which we have to contend."

As Sir Stanford Cade, the chairman of our symposium of this afternoon, wrote: "The review of the hazard to which the patient is exposed, never deliberately . . . is a melancholy clinical exercise, but is nevertheless salutary." In the ninth Crookshank lecture Sir Stanford was directing his remarks to some of the iatrogenic diseases which may follow irradiation; most of these are the results of scarring or fibrosis, and well-nigh any tissue may suffer. These effects may be avoided by changes in technique, in timing, in fractionation of dosage, or by using other therapeutic measures—perhaps combined with irradiation.

Positive Health and Leisure

I have spoken of positive health. We all know that this will not come from the National Health Service, which is far more a national disease service. Positive glowing health is much more than a rather negative disease-free state.

At the Saturday evening meeting the subject was "Religion and Health." Speakers set out to show that a state of real health of mind and body may best be reached and kept when we have come to terms with the problems of life and death. The service at the cathedral was an act of unified worship and prayer for the "Hallowing of Medicine," the like of which we have not seen before.

Sir Ian Fraser's last paragraphs were about leisure, the need, and the way to spend it. The maintenance of full health usually requires some form of recreation. Your Thursday afternoon will be taken up by a symposium on this very subject. Well-known experts will be speaking on some of the many ways of pursuing other interests than our work, for, however much we are devoted to that work, we need these outside interests if we are indefinitely to maintain a full service in our profession. We may not yet have a professor of leisure, but universities nowadays provide means and incentives for the enjoyment of leisure, and you will have noticed that in this regard our university is not lagging behind.

The session on vocational practice will indicate that special sense of satisfaction which is derived from devotion to, and a real sense of vocation in, our work, which we intend to *enjoy* not only for our own sakes but for the sake of those who seek our help.

The doctor will always have to be something more than the latest computer. Science will always have its limitations. The doctor must bring to his job the highest ethical standards, the deepest sense of personal responsibility, and a readily felt warm humanity. You will remember the result of a British Medical Association inquiry of some fourteen hundred schoolmasters regarding what qualities they thought important in the boy intending to practise medicine. In a formidable list emphasis was laid on loyalties, perseverance, poise, conscientiousness, resourcefulness, sympathy, patience, compassion, gentleness, and imagination. Some of these are the more intangible things to which Sir George Pickering referred and was so concerned lest we lost these precious assets in our search for science and truth.

To quote again from William Stokes (1867). "When medicine is in a position to command respect be sure that it will be proportionately increased, and its status elevated." And for many decades that respect and regard was ours, sometimes almost automatically. We held an enviable position in society. Now in 1967 how do we stand? Certainly there is no automatic respect or regard today; these must be merited, but they can be won, and kept.

The Written Word

It is customary to publish this address, and there is no escape from tradition. I had many great teachers who taught me to *do* things well, but there is comfort from Keats, who said, "I am convinced that fine writing is, *next* to fine doing, the top thing in the world."

However, it is a duty to publish critical accounts of experiences which may be of far greater value than we may think at the time. As Byron once said: "A small drop of ink, falling like dew upon a thought, produces that which makes thousands, perhaps millions, think." "Written words are dangerous," said Richards, so it behoves us to go into print with caution. What little I have written has never satisfied me. Yet three years ago when, without warning, I visited a surgeon in Colombo he told me that by a strange coincidence only a few days previously he, with his surgical team, had referred to something I had written in 1952, and, as the result, they had proceeded successfully to remove an advanced malignancy of the colon.

You will notice that I have quoted extensively from the works of others—only a few crumbs are my own. It is said that to copy from one book is cheating, to copy from two or more books is research.

At Londonderry someone said that coffee was essential to family practice—referring to the quite splendid medical centres springing up all over the country, where all can meet, family doctors, consultants, and others. There they can chat, learn to know each other, and learn to be concerned for each other. The "happy ship" was mentioned—perhaps a bit wistfully. Surely we should be just that.

Conclusion

In summary, then, free from any threat of disintegration and speaking with one voice, our great and noble profession, unified not only by loyalties and concern for each other but by its one great unifying purpose, will give a service which will still be the envy of every country in the world—the pattern which others will seek to follow.

Perhaps, even unwittingly, as we are more and more concerned for others we shall in fact be following more nearly the pattern of that incomparable life of concern for others. You will remember how our Lord answered the question—

"*When* saw we Thee sick and came unto Thee . . . ?"

"Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto Me."

Dietetic Treatment of Phenylketonuria: a Follow-up Study

BARBARA CLAYTON,* M.D., PH.D., M.R.C.P.; ALAN MONCRIEFF,† C.B.E., M.D., F.R.C.P., F.R.C.O.G.
G. E. ROBERTS,‡ M.B., B.CH., D.P.M.

Brit. med. J., 1967, 3, 133–136

This is a factual study of 57 children with phenylketonuria (31 boys and 26 girls) seen during the period 1955 to the end of 1965. Most of them were under the care of one of us (A. M.), but other physicians at the Hospital for Sick Children have allowed us to use their records. With this small number under various physicians, the reasons for not treating some children or terminating treatment in others necessarily varied. Only those who were treated, or at least given a trial of treatment, are included in this report. Some patients born or detected late in 1965 were not included, as the results obtained were too recent for any satisfactory assessment. One patient (Case 55), detected at 6 years and 4 months, had an I.Q. of 105 and is the subject of a special note.

Methods of Treatment

The basis of the dietetic treatment of phenylketonuria is the exclusion of phenylalanine from the diet save for a minimal amount necessary to sustain life and progress. After a positive test for phenylpyruvic acid in the urine, confirmation is sought by examining the phenylalanine content of the blood. Normally this is about 2 mg./100 ml. serum when a chromatographic method of estimation is used, but in affected children it is much higher. The aim of dietary treatment has been to maintain the level below 4 mg. It is generally advisable to admit the child to hospital for "stabilization."

In the early days of the treatment, when affected children mostly past infancy were being discovered and treated, the practice was to eliminate all phenylalanine by using a synthetic "milk" very low in phenylalanine and a careful selection of other items free from or very low in phenylalanine. When a satisfactory low blood level had been achieved—and sometimes this regimen resulted in the complete disappearance of phenylalanine from the blood—ordinary cow's milk (liquid or dried) was added to the diet until the level of phenylalanine rose; but such a rise was restricted to a maximum of 4 mg./100 ml. serum and the amount of milk adjusted accordingly by frequent estimations of the serum phenylalanine level. An early account of experience in this programme at the Hospital for Sick Children has been published (Woolf, Griffiths, and Moncrieff, 1955). Further experience led to a full account of the methods used and the results achieved (Woolf, Griffiths, Moncrieff, Coates, and Dillistone, 1958).

When treatment of quite young babies was started, however, complete exclusion of phenylalanine from the daily diet produced alarming results, which included skin rashes, loss of appetite, and wasting. An account of some of these difficulties was published (Moncrieff and Wilkinson, 1961). Because of these findings it is necessary to add a calculated amount of milk to the diet, the basis of which is one of the special casein hydrolysates. Full accounts of the methods used have been published as a report of a conference to the Medical Research Council (1963). A short, simple account of a method for feeding the phenylketonuric infant was published from the Hospital for Sick Children by Clayton, Francis, and Moncrieff (1965). It can be assumed that all the children whose cases are reported in the present series have been treated according to the methods in the publications cited.

No mention is made here of methods employed elsewhere than at the Hospital for Sick Children, as this is essentially a report of personal experiences. For the same reason no attempt has been made to review the literature.

The main detailed results are shown in Table I, and the patients are arranged in order of the age of detection, beginning with the youngest. The "quality" of treatment

Table I.—*Summary of Effect of Treatment*

Case No.	Age Detected (Weeks)	Initial I.Q.	Duration of Treatment (Weeks)	Quality of Treatment	Last I.Q.	Epilepsy	Placement

56	450	49	320	Fair	45	–	Preschool
57	496	47	28	Abandoned	49	–	T.C.

Ordinary school indicates placement with the normal educational system.
E.S.N. indicates placement in a school for the educationally subnormal.
T.C. indicates placement at a training centre.
Hospital indicates placement in a hospital for the subnormal.
Rudolph Steiner indicates placement in a special unit.

---

* Consultant Chemical Pathologist, the Hospital for Sick Children, Great Ormond Street, London W.C.1.
† Formerly Nuffield Professor of Child Health, University of London, and Physician, the Hospital for Sick Children, Great Ormond Street, London W.C.1.
‡ Physician Superintendent, the Ida Darwin Hospital, Fulbourn, Cambridge.

was assessed as good, fair, or bad. This assessment is necessarily subjective, but it was made from our knowledge of the parents together with the views of the ward sister and the dietitians. Thus in 40 instances the standard of maternal care was good, in 15 it was fair, and in two the treatment was abandoned.

Intelligence Testing

The assessment of developmental progress and/or intelligence in children of all ages, but especially in the neonatal period, is fraught with difficulty. Nevertheless, in assessing the progress of children being treated for phenylketonuria, some objective evaluation has to be made, though the limitations of such procedures are well recognized. In particular the standard tests used do not measure the more subtle aspects of behaviour and "intelligence" that may result from dietary treatment.

In the longitudinal study various tests have been used, depending on the age of the child. These tests have included the Griffiths, the Stanford–Binet, the Merrill–Palmer, and the Wechsler. For the purpose of this paper the "score," whatever the test, is expressed as "I.Q." for reasons of convenience.

It must be recognized, however, that the determination of an I.Q. in numerical terms is related to placement within the educational system. It may be that in future, for infants and small children, the term "developmental" tests would be more appropriate.

In the early days in the treatment of phenylketonuric children, before screening tests were introduced on a more or less national scale, it was surprising to find such variable levels of intelligence at the initial testing. One child (Case 55), with an I.Q. of 105 at the age of 321 weeks, has already been mentioned, and this case has been fully reported (Coates, Norman, and Woolf, 1957).

Case 55.—A boy, the fourth child of a family of five, was affected by Gowers's muscular dystrophy. At the time of this diagnosis, when he was 6 years old, the urine was examined for amino-acids, and phenylpyruvic acid was detected. The level of phenylalanine in the blood was raised. Other children in the family were given intelligence tests and were all higher in rating than the patient. It is perhaps significant that just over two years after the initial intelligence testing the level in this patient had fallen by an average of 18 points and a low phenylalanine diet, previously abandoned after three months, was reinstituted.

The parents of this child had above average levels of intelligence, especially the mother. Unfortunately, the intelligence level of other parents in the present series was not estimated.

Effects of Treatment

In general terms the best results, as might be expected, were obtained when treatment was started in early infancy, though some surprisingly good results were obtained in older children, with a rise in intelligence level which enabled them to go to a school for the educationally subnormal (Cases 18, 19, 21, 44, 46, 48, 49, 52, and 53) and to an ordinary school (Cases 2, 12, 13, 15, 20, 31, 38, 39, 41, 47, 51, and 55). Some of these results are shown in the Chart. The final placements of all the children are shown in Table I.

Additional Comments

The reasons for referral to hospital are shown in Table II, which illustrates clearly that the patients are by no means always referred because of mental subnormality alone. Table III shows how and where the disorder was initially diagnosed. It was disappointing to find that during the whole period only 10 patients were detected in infant welfare centres and only two of these were under 6 weeks of age. Seven were detected because of the presence of a previous sibling with the condition, five in the first three weeks of life, and these have done well. The majority, however, have been detected because of the presence of mental subnormality, unfortunately only becoming apparent from 6 months of age onwards.

TABLE II.—*Main Reasons for Referral to Hospital*

Mental subnormality		32
Epilepsy (in each case "infantile spasm")		4
Failure to thrive		3
Speech retardation		1
Eczema		2
Muscular dystrophy		1
Asymptomatic	1. From infant welfare centre	7
	2. Known to be "at risk"	7
	Total	57

TABLE III.—*How, Where, and Why the Diagnosis Was Made*

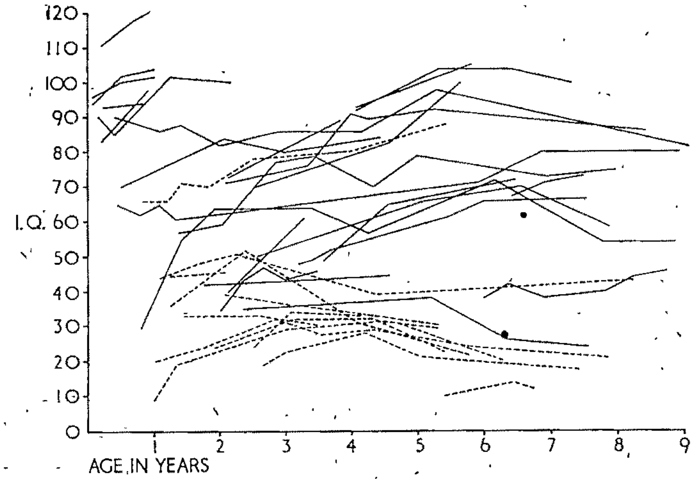
Age	Infant Welfare Centre		Hospital Services			Health Visitor ? M/S	Family Doctor ? M/S
	Routine	? M/S	Routine Investigation	Screened for M/S	At Risk Child		
<3 weeks	1				5		
3–6 weeks	1						
6–8 „	3						
8–12 „	1						
3–6 „	1		1		1		
6–9 months			1	4		1	
9–12 „				3			1
12–18 „		1	1	8			
18–24 „				3			
2–2½ years		2		6			
2½–3 „				3	1		
3–4 „			1	2			
4–5 „				1			
5–6 „							
6–7 „			1	1			
7–8 „							
8–9 „				1			
9–10 „				1			

M/S = Mental subnormality. At risk = Previously affected sibling.

Reasons for failure or partial failure of the treatment are perhaps as important as reasons for success. Several possibilities, or associated phenomena, must be taken into account when assessing the progress of an individual child.

1. *Epilepsy.*—All but three children with epilepsy appear to have responded badly to dietary treatment (see Table I). Eighteen of the 57 children suffered from epilepsy. The progress of some of these is shown in the Chart. A statistical analysis was carried out to see whether the final I.Q. score differed in the two groups of children (epileptics and non-epileptics) after adjusting for initial I.Q., duration of treatment, and age at detection. The results of an analysis of convariance were as follows:

(F-test) $F = 14.6$ (D.F. 1,49)
Very highly significant; $P < 0.001$.
Difference between groups for adjusted final I.Q. = 16.4



Developmental progress of the patients on treatment who had been regularly assessed. ——— Denotes non-epileptics. - - - - - Denotes the presence of epilepsy.

Hence the results indicate that the final I.Q. is higher in non-epileptic children after allowance is made for initial I.Q., duration of treatment, and age at detection. The type of epilepsy and the ages of onset are shown in Table IV. The high incidence of infantile spasms is noteworthy.

TABLE IV.—*Type of Epilepsy and Age of Onset*

Type of Epilepsy	Age of Onset (Months)						Total No.
	5	6	7	8	9	12–18	
" Infantile Spasms "		2	1	1	4	2	10
Grand mal	1				2	3	6
Petit „						2	2

2. *Infection.*—Because the blood phenylalanine level is found to rise temporarily during acute infections, it was thought that the presence of chronic infection—for example, chronic tonsillitis or discharging ears—might militate against the success of dietetic treatment in keeping the blood phenylalanine at a satisfactory low level. So far as the records examined show, however, there was no evidence of this.

3. *Dietetic Difficulties.*—Difficulties with the diet were not infrequently present, often requiring admission to hospital for further stabilization, but, unless breaks in diet lasted more than a week or so, no obvious unsatisfactory results were observed. Infants and young children alleged to refuse the special diet took it in hospital, and intensive instruction of the mothers was necessary. Children of school age presented some difficulties over the midday meal at school, but the education authorities and teachers were always most helpful. Occasional raiding of the larders at home probably does no permanent harm. It is interesting to note that in two affected young children there was a clear history of a severe dislike for ordinary milk from an early age, and later for all protein-containing foods, including eggs. A few parents either refused to co-operate or claimed that it was impossible to get the children to take the special diet. This was the case in certain older children rather than in babies. In one instance the reason given was that a child was no more backward than an elder sister. Investigations showed that the latter child was also affected and untreated. They were members of a migrant gipsy family and were best left alone.

Physical Progress

The records examined have not always shown details of height and weight. When available, heights and weights were converted into percentile groups (Tanner and Whitehouse, 1959). The results are shown in Table V. In general there is no evidence that phenylalanine-restricted diet resulted in poor physical development. In the case of twins, one of whom was affected and treated from the age of 17 days (the other twin being normal), the treated child at the age of 9 was actually 1 in. (2.5 cm.) taller than her sister.

TABLE V.—*Height and Weight of Treated Patients*

Percentile Status	No. of Patients

75–89	2	1
90–96	—	3
97 and over ..	1	2
Total ..	57	57

Criteria for Treatment

In the early days of the treatment of phenylketonuria patients, most of the children found with this abnormality were past the age of infancy, and some " rule of thumb " had to be devised. As experience developed it seemed likely in most instances that a rise of about 20 points in the intelligence level might be achieved by treatment, and even if this did not raise the child into the educational level (educationally subnormal or fit for ordinary school) it seemed worth while even to raise the child from the severe to the moderately subnormal level. In the report of Woolf *et al.* (1958) a rough guide was set out as follows: " We consider treatment worth initiating if the child is 2 years old or under and the G.Q. not less than 20, or 3 years old with a G.Q. of 30 or over, or 4 years old with a G.Q. of 40 or over. In any border-line cases it is probably wise to try six months' treatment with careful psychological testing at the beginning, at 3 months and at the end of this period."

The paper went on to state that it was important to rule out any other form of brain disease such as that due to birth trauma in the widest sense. In the light of further experience it is probably wise to add that the presence of " fits " would make a favourable outcome unlikely. With this reservation, however, it would be fair to state that the policy set out in 1958 is still valid. In addition, all young babies detected by routine screening should certainly be treated.

When to Stop Treatment

This question is of increasing importance as the number of children under treatment grows and the children get older. We have not felt that ethically we could yet stop treatment in any of the patients here reported as doing well. Theoretically it is possible that there is a point in maturation of the brain when a raised phenylalanine level in the blood ceases to cause damage or, to put it another way round, the brain cells develop some degree of tolerance. An attempt to test this by a consideration of the immediate effects of a dose of phenylalanine on the electroencephalogram has been made in the department of electroencephalography at the Hospital for Sick Children (Clayton, Moncrieff, Pampiglione, and Shepherd, 1966). Twelve children received dietetic treatment for phenylketonuria were selected and in seven a considerable increase in the abnormality of the electroencephalogram occurred after a phenylalanine load. It would seem unwise to relax dietetic restrictions in these children. Five children showed only mild or negligible changes during the phenylalanine-tolerance test. These were all children whose intelligence quotients at the time of the test were around normal. Three had started treatment in the first two months of life, and in the other two, though starting treatment at nearly 2 and 3 years old respectively, a remarkable improvement had occurred in their measured intelligence levels. Even in these children we are still hesitant to increase their phenylalanine intake at present.

Summary

From 1955 to the end of 1965 57 children with phenylketonuria, who were treated or at least given a trial of treatment, were studied.

Only 10 of the patients were detected in infant welfare centres, and only two of these were under 6 weeks of age. Seven were detected because a previous sibling had the condition. Unfortunately, the majority were discovered after mental subnormality had become apparent.

The best results were obtained when treatment was started in early infancy.

Sometimes surprisingly good results occurred in older children, with a rise in intelligence level which enabled them to go to a school for the educationally subnormal or to a normal school.

All but three of the 18 children with epilepsy responded badly to dietary treatment.

There was no evidence that dietary treatment resulted in poor physical development.

Thanks are due to the physicians at the hospital for permission to study their patients; to Mr. H. Goldstein for help with the statistical analysis; to the staff of the Department of Psychological Medicine for their interest in the psychometric testing; and to the dietitians and ward staff for their co-operation in the treatment of the patients. We are grateful to the Nuffield Foundation for financial assistance.

Studies in the Epidemiology of Tinea Pedis. VIII: Fungal Infection in a Long-stay Hospital

MARY P. ENGLISH,* M.SC.; R. R. WETHERED,† B.A., B.M., B.CH.; ETHEL H. L. DUNCAN,‡ M.A., B.SC.

Brit. med. J., 1967, 3, 136–139

Tinea pedis has been studied in many different types of community, each yielding different but complementary information about the epidemiology of the disease. It now seems certain that the most common means of transmission is the direct contact of healthy feet with small fragments of skin shed by infected persons (Gentles, 1957; English and Gibson, 1959b; Gip, 1966). This may happen in various ways, the relative importance of which will differ in different communities. It is also known that the incidence of infection is higher in persons living a communal life (Marples and di Menna, 1949; English, Gibson, and Warin, 1961; Wrede, 1965) or using communal washing facilities or swimming-baths (Tritsmans and Vanbreuseghem, 1955; Gentles and Holmes, 1957; English, Gibson, and Duncan, 1960) than in those not doing so; and that, in children, incidence rises with age (English and Gibson, 1959a; Munro-Ashman and Clayton, 1962; Polemann, 1955). There is dispute about the extent to which fungi are carried on, and hence dispersed by, lesion-free feet (Rosenthal, Baer, Litt, Rogachefsky, and Furnari, 1956; English, 1962). That many people have a natural resistance to the disease is a constantly observed fact, though the nature of this resistance and the proportion of the population protected by it are unknown.

The two fungi responsible for the overwhelming majority of cases of tinea pedis in this country are *Trichophyton interdigitale* and *T. rubrum*. The incidence of *T. rubrum* is increasing rapidly, and recent figures from dermatological clinics in Bristol show that it now occurs more often in them than *T. interdigitale*. However, English and Gibson (1959a) and English *et al.* (1961) have shown that both in day schools and in boarding-schools *T. interdigitale* was by far the most common fungus, and this has been confirmed in another boarding-school by Munro-Ashman and Clayton (1962). Similar figures for a sample of the adult population not attending skin clinics are not available, but English and Turvey (work to be published) have recently shown that in patients attending a chiropody clinic, almost entirely for complaints other than tinea pedis, 20 of the 33 infections found were attributable to *T. interdigitale* and only five to *T. rubrum*. *T. interdigitale*, therefore, is still the most common cause of tinea pedis in the population at large. *Epidermophyton floccosum*, the third causal organism, is comparatively rare and its incidence seems to be changing little. The clinical manifestations and epidemiology of these three species differ, but only very tentative suggestions regarding the reasons for this have been put forward.

It seemed possible that information on some of the above points might be provided by the study of a large, relatively stable community of adults living communally for most or all of their lives. During 1964 the attention of one of us (R. R. W.) had been attracted by the large number of patients in one section of a long-stay hospital for mentally retarded men who had clinically severe tinea pedis, and it was decided that a detailed epidemiological study of this hospital should be undertaken.

Subjects

The hospital housed some 400 male patients of all degrees of mental subnormality, some of whom also had mild to severe physical handicaps.

Patients were grouped in "lodges," each housed in separate buildings or parts of buildings. Lodge 7, the largest, was also used for the supervision and discipline of difficult patients, and it was therefore likely that patients from most other lodges spent periods there. Other transfers between lodges occurred at intervals, but many patients had been in the same lodge for a very long time. Lodge 9 was reserved for the elderly sick.

Lodges 7 and 8 each had a 60-bed dormitory; other dormitories ranged in size from 6 to 24 beds. Bathrooms were communal and each contained a number of baths. Up to the end of 1964 one bathroom served lodges 1–5, another lodges 6–8, and lodge 9 had its own. In December of that year additional bathrooms were brought into use so that one was shared by lodges 1 and 2, another by lodges 3–5, and lodges 6, 7, and 8 had one each.

Of the 358 patients included in the survey, 7 were under 20 years old and 276 (77%) were over 40; 326 (91%) had lived in the hospital for three years or more and 236 (66%) for 11 years or more.

---

* Mycologist, Bristol Royal Hospital.
† General Practitioner, Bristol.
‡ Senior Lecturer in Medical Statistics, University of Bristol.

Patients were bathed twice weekly, clean socks and towels being issued after each bath. Towels were likely to be shared and used as bath mats; socks (which were all woollen) were not shared between launderings, but patients did not have their own towels or socks, which were laundered centrally and reissued indiscriminately. Each patient had his own slippers or house shoes, but these were not marked, as were other clothes. In fact, patients rarely wore them and often walked about in the dormitories bare-footed.

Clinical, Laboratory, and Statistical Methods

Scrapings were taken from 358 patients during the summer of 1965 by two of us (M. P. E. and R. R. W.) with the assistance of two registrars in dermatology. Patients omitted from the survey were either on licence or on holiday. Clinical details were taken down by nurses from the hospital. The feet and hands of all patients were examined and samples taken from all lesions of skin or nails which might possibly be attributed to fungal infection; if there were no such lesions, or if only nail lesions were found, scrapings were taken from webs between the fourth and fifth toes.

Details of the patient's age, length of residence at the hospital, lodge, physical capability, abnormalities, etc., were collected by the hospital's nurses from the patients' notes.

Laboratory investigations were carried out by M. P. E. Scrapings were cultured the day after they were taken. All were plated on glucose-peptone agar with chloramphenicol and cycloheximide and incubated for at least one week at 29° C.; further fragments of those from which no dermatophytes grew were then examined microscopically in 20% potassium hydroxide. In a number of cases in which a fungus was seen on microscopy but cultures had failed it was possible to obtain fresh scrapings from which the fungus was successfully isolated.

Nails which were positive on microscopy but not in culture were examined for non-dermatophyte fungi by replating them on cycloheximide-free medium, but were regarded as infected by these fungi only if at least 5/20 inocula yielded the same organism.

Cultures from patients' socks were made (1) by shaking or scraping them over plates of glucose-peptone-cyclohexamide-chloramphenicol agar (Broughton, 1955) and (2) by soaking small pieces of the fabric in the cooled molten medium and pouring-plates. Both methods were satisfactory.

The planning of the survey and the analysis of results were the responsibility of the third author (E. H. L. D.). The questionary used for recording patients' histories and laboratory and clinical findings was prepared in such a way that the replies could be used for punched-card analysis without further coding.

Mycological and Clinical Results

Table I shows the number of patients infected with each fungus or pair of fungi, and also the number of isolations of each organism. *T. interdigitale* was the dominant species, but a high percentage of *T. rubrum* was also recorded; *E. floccosum* was comparatively rare. Isolates of *T. interdigitale* varied considerably in appearance, but the variations were not constant on subculturing. *T. rubrum* isolates, on the other hand, were almost all of the same distinctive type, which remained constant over many subcultures. The strain was very strongly pigmented and was unusual in being intermediate between the "granular" and "downy" types (English, 1964). All non-dermatophytes were found in toe-nails; that there were no *Aspergillus* spp. is unexpected (Walshe and English, 1966). The culture failure rate of 7.5% was well within normal limits.

TABLE I.—*Incidence of Infections and Number of Isolations Among* 358 *Patients Examined*

Total	146	40·8	163	

*All from toe-nails. *Scopulariopsis brevicaulis*, 2 isolates; *Fusarium* sp., 1 isolate; *Cephalosporium* sp., 1 isolate; *Penicillium* sp., 1 isolate; cultures failed, 2.

Double infections, either concurrent or combined (Partridge, 1952), were found in 17 (11.7%) of infected patients, and their occurrence was not related to the length of the patient's stay in hospital, his age, or the incidence of fungi in his lodge, all factors affecting opportunity for cross-infection. This contrasts with the observations of Gentles and Holmes (1957) in coal miners, and suggests that lack of resistance in the patient may also be a factor in the occurrence of double infections.

Table II shows the sites infected by dermatophytes only. The hands were involved in 6 out of 140 patients with tinea pedis; in addition, one patient had also had a widespread infection with *T. rubrum* the previous year, which had responded to treatment. Nurses reported that groin infections, which they would probably notice while bathing patients, were not very common; if this was so it was unexpected in view of the high incidence of *T. rubrum* in the feet (English and La Touche, 1957) and the common occurrence of tinea cruris in all-male communities.

TABLE II.—*Sites of Infection (excluding non-dermatophytes) Among* 358 *Patients Examined*

Site	Patients Infected	
	No.	% of Total Patients
Feet only	91	25·4
Feet and toe-nails	34	9·5
Toe-nails only	9	2·5
Feet and hands (including finger-nails)	1	0·3
Feet, toe-nails, and hands (including finger-nails) ..	5	1·4

The clinical behaviour of *T. interdigitale* and *T. rubrum* is compared in Table III. The results confirm the observations of others that *T. rubrum* tends to cause extensive infections while those of *T. interdigitale* are more restricted. Toe-nails were involved in 19 out of 89 (21%) *T. interdigitale* infections and 21 out of 51 (41%) *T. rubrum* infections: in 3 out of 19 cases of *T. interdigitale* infections of this site the skin of the feet was not affected, but all *T. rubrum* infections of the toe-

nails were part of a more widespread condition. All hand infections were attributable to *T. rubrum*.

Dermatophytes were present in the lesion-free toe-webs of 19 patients; 17 of these had *T. interdigitale*, one *T. rubrum*, and one a fungus found on microscopy only. Three of the *T. interdigitale* infections were associated with clinical onychomycosis caused by the same fungus, and here the nails were obviously the source of contamination. The great preponderance of *T. interdigitale* over *T. rubrum* (Götz, Sturde, and Hantschke, 1965) probably reflects the comparatively mild nature of infections due to the former fungus and perhaps a tendency to spontaneous resolution. The occurrence of lesion-free infections was unrelated to the age of the patient, the length of his stay in hospital, or the incidence of infections in his lodge.

In view of the differences of opinion on the importance of lesion-free carriers in the epidemiology of tinea pedis, 17 of the above patients were re-examined after one year: 10 were found to be still infected, but to have developed lesions; six were no longer infected; and one (*T. interdigitale*) remained infected without lesions. Most cases of apparent toe-web "carriers," therefore, were probably simply stages in the onset or regression (Svendsen, 1961) of an infection, or contamination from a clinical infection of the nail; only one patient out of 358 could be regarded as a carrier in the usual sense. This is a lower rate than that found by Götz and Hantschke (1965) in a similar investigation on coal miners. These workers reported that 41 out of 1,240 (3%) carried dermatophytes asymptomatically over a period of a year; they do not, however, state whether any of these men had toe-nail infections.

Epidemiological Results

Table IV shows that the incidence of infection varied very appreciably from lodge to lodge. However, probability tests showed that for *T. interdigitale* all such interlodge variation could have occurred by chance; for *T. rubrum* only, the incidence in lodge 7 was significantly different from that in other lodges ($P<0.05$), and, for the total fungi, the incidence in lodge 1 was significantly higher than in other lodges ($P<0.01$). The ratio % *T. rubrum*/% *T. interdigitale* for lodge 7 was 1/0.95; that for all other lodges combined was 1/1.91—that is, the proportion of *T. rubrum* infections in lodge 7 was significantly higher than that in other lodges ($P<0.05$). There was no significant difference in average incidence in patients using different bathrooms, either when grouped according to bathrooms in use up to and during 1964 (Table IV) or when the new bathrooms in use after this date were considered.

Figures in italics are statistically significant (see text).

Other factors investigated and found to be unrelated to the incidence of infection were size of dormitory, patient's age, mongolism, deformities of the feet (Svendsen, 1961), and mobility. With regard to mobility, it was found that of nine patients who had been unable to walk from birth, four had tinea pedis.

A long stay in hospital was found to increase significantly the likelihood of infection. Of 31 patients who had been in residence for under three years, 6 (19%) were infected; while of 327 who had been in residence for a longer period 134 (41%) were infected ($P=0.02$).

Hyperhidrosis appeared to inhibit fungal infection, for none of the 12 hyperhidrotic patients had the disease ($P=0.00164$ by Fisher's exact probability test).

Toe-nail infections were found to be unrelated to the length of the patient's stay in hospital, but those due to *T. rubrum* and total fungi (including non-dermatophytes) were significantly related to the patient's age (Table V) (Rosman, 1966; Walshe and English, 1966). The incidence of onychomycosis due to *T. rubrum* was significantly higher in lodge 7 than in all other lodges, but that of *T. interdigitale* onychomycosis was not (Table VI).

Cultures were made (1) from one pair of socks from each of three patients with *T. interdigitale* infection and one pair from a patient with *T. rubrum* infection after they had been worn for four days and (2) from another pair of socks from each of the same patients after these had been worn for four days and washed in the hospital laundry. The appropriate fungus was recovered from all the unlaundered socks, and a few colonies of *T. interdigitale* were also obtained from those of the *T. rubrum* patient in addition to his own fungus, presumably a legacy from the previous wearer. After laundering, a few colonies of *T. interdigitale* were isolated from the socks of one of the *T. interdigitale* patients, but cultures from the other socks were negative. Thus laundering considerably reduces the quantity of potential inoculum in socks but does not eliminate it.

Discussion

When this survey was undertaken it was supposed that all the conditions making for the highest possible incidence of tinea pedis would be present. In fact, the average incidence of all dermatophytes, 39%, was lower than that in miners in one of the pits investigated by Gentles and Holmes (1957) (57%) and also than that in pits in the Ruhr (69%) (calculated from Götz *et al.*, 1965). However, the incidence in lodge 1 of the hospital (66.6%) was significantly higher than that in other lodges and of the same order as that in miners. It may be, therefore, that conditions in lodge 1 were such that a near maximum level of infection had been reached and that, left unchecked, the same level would eventually be attained throughout the hospital. In view of the coincidence of the figures for patients in lodge 1 and of those for miners it is possible that the number of persons remaining uninfected, 30–40%, represents the proportion of persons in the adult male population who are resistant to tinea pedis. The nature of this resistance is a matter of speculation (Munro-Ashman and Clayton, 1962), on which this survey throws no light; but so high a figure would explain the great difficulty found by workers who have tried to establish experimental infections in human feet (Baer, Rosenthal, Rogachefsky, and Litt, 1955; Strauss and Kligman, 1957).

Some interesting aspects of the epidemiology of the two dominant fungal species are brought out by this survey. That there was no statistically significant difference in the incidence of *T. interdigitale* in the different lodges suggests that the fungus had been present for a long period, probably with repeated introductions, leading to an even spread throughout the community. The instability of the *T. interdigitale* isolates in culture prevented any speculation over the introduction of different strains of that fungus. The *T. rubrum* isolates, however, were not only stable on subculture but were almost all of the same distinctive type, intermediate between the well-recognized "granular" and "downy" forms, a type rarely found in diagnostic practice in the district (English, 1964). This suggests a single introduction at some time in the past which spread through the community, possibly followed by more recent introductions of other forms which have not yet had time to spread. The idea of early, multiple introductions of *T. interdigitale* but a single, more recent introduction of *T. rubrum* is compatible with knowledge of the relative incidences of the two species in the population at large (see introduction) and with the fact that *T. rubrum* has only recently reached even its present incidence in this country.

Patients in the closest contact with the original case of *T. rubrum* infection would be likely to become infected before those less close, and, once infected, their condition would not regress spontaneously. Therefore, supposing that there had not yet been time for all susceptible patients to have contracted the disease, the original introduction would have occurred in the lodge with the highest infection rate. This is lodge 7, the only one in which both the *T. rubrum* infection rate and the *T. rubrum/T. interdigitale* ratio were significantly higher than in all other lodges. *T. rubrum* infections in lodge 7 were also clinically more extensive and conspicuous than elsewhere (this being the lodge that originally drew the attention of R. R. W. to the problem of tinea pedis in the hospital), and were therefore likely to have been established longer, as was confirmed by the abnormally high incidence of *T. rubrum* onychomycosis in this lodge compared with an average incidence of *T. interdigitale* nail infections.

Cross-infection in the hospital must obviously have occurred by a number of routes. Within lodges it would have taken place in the dormitories, where the patients were often barefooted. Scissors used for cutting the patients' nails might also be implicated, though these were not examined. But if the bulk of the *T. rubrum* infections were indeed the result of a single introduction, these must also have been spread between lodges. This could partly be accounted for by the transfer of patients from lodge to lodge and also, between groups of lodges, by the sharing of bathrooms up to 1964, though the latter effect must have been comparatively slight as no statistical significance could be shown. As well as being probably of minor importance generally, neither of these two routes accounts for the fact that, out of nine crippled patients who had never walked, four had tinea pedis. Broughton (1955) has shown that dermatophyte fungi can be isolated from the socks of infected persons both before and after laundering, and we have confirmed this. It seems probable that the custom in this hospital of the communal ownership of socks and towels must have been an important factor in the spread of tinea pedis: in fact, if the high incidence of infection in crippled patients is any guide, it was probably the most important route between lodges. Though Broughton (1955) and Sanderson and Sloper (1953) suggest that socks are a likely means of cross-infection, our observations are probably the first to offer strong evidence that this was so in a particular community.

Summary

The incidence of tinea pedis, including tinea unguium, in a long-stay hospital for mentally retarded men was 40.8% of 358 men examined. Of the infections, 50% were attributable to *Trichophyton interdigitale*, 26% to *T. rubrum*, 0.7% to *Epidermophyton floccosum*, 4.1% (nails only) to non-dermatophytes, 11.7% to mixed infections, and 7.5% were microscopically positive but cultures failed.

The incidence of *T. rubrum* was significantly higher in patients in one of the "lodges" into which the hospital was divided than in the others, but there was no significant difference in the incidence of *T. interdigitale* infections in lodges. Infection was related to the length of the patient's stay in hospital but not to his age, the communal bathroom used by him, or other factors examined. Four out of nine crippled patients who had never walked had tinea pedis. The appropriate fungus was isolated before laundering from the worn socks of three patients with *T. interdigitale* infection and of one patient with *T. rubrum* infection; after laundering the fungus was recovered from the socks of one of the patients with *T. interdigitale* infection.

In view of the failure of laundering to eliminate the fungus from worn socks, of the fact that socks were not the property of patients but were reissued indiscriminately after laundering, and of the high infection rate in patients who had never been able to walk, it is suggested that infected socks were a more important route of cross-infection in this community than contaminated floors.

We are indebted to Dr. R. P. Warin, Bristol General Hospital, for initiating this survey and for his suggestions and encouragement throughout. Our thanks are due to Dr. T. C. Leahy for allowing us access to the hospital and for putting every facility for the investigation at our disposal; to the nursing staff of the hospital for their invaluable co-operation and interest; to Mr. T. G. Morgan, who carried out a great deal of the laboratory work; and to Dr. M. M. Walshe and Dr. R. Heeler for assistance in taking the scrapings.

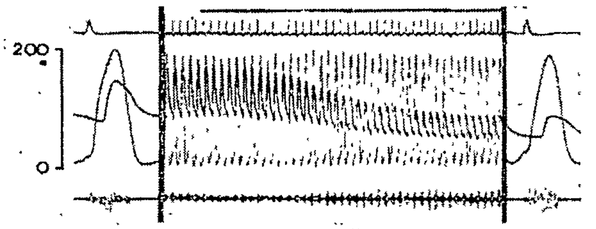
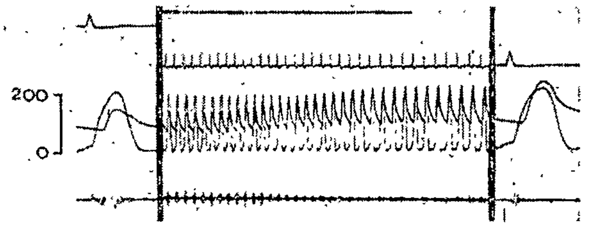
Brit. med. J., 1967, 3, 140–143

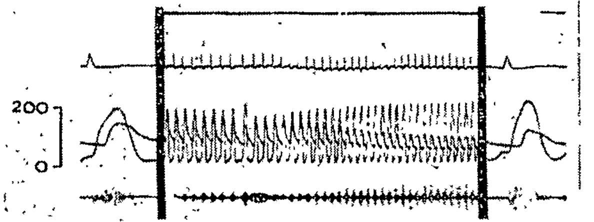
In patients with hypertrophic obstructive cardiomyopathy obstruction to left ventricular ejection varies from moment to moment. The pressure gradient can be increased by amyl nitrite, which lowers peripheral resistance (Braunwald and Ebert, 1962; Wigle *et al.*, 1965; Hancock and Fowkes, 1966), or can be reduced or abolished by systemic vasoconstriction with phenylephrine, methoxamine, or angiotensin (Braunwald and Ebert, 1962; Braunwald *et al.*, 1964a; Wigle *et al.*, 1965) or by aortic constriction (Pierce *et al.*, 1964). Inotropic agents—digitalis and isoprenaline—increase the obstruction by increasing the vigour of ventricular contraction; this effect can be prevented by drugs which block the sympathetic beta-receptors (Braunwald and Ebert, 1962; Braunwald *et al.*, 1962; Harrison *et al.*, 1964). Reduction in circulating blood volume and the Valsalva manœuvre reduce ventricular volume, increase contractility, and increase the obstruction (Braunwald *et al.*, 1964b; Marcus *et al.*, 1964; Shah *et al.*, 1965a, 1965b). During these manipulations of the circulation the murmur varies in intensity, becoming louder with more severe obstruction, and can be virtually abolished when the gradient disappears (Goodwin, 1964; Nellen *et al.*, 1965) (Fig. 1), thus reflecting the haemodynamic situation.



AMYL NITRITE



PHENYLEPHRINE



ISOPRENALINE

FIG. 1.—Hypertrophic obstructive cardiomyopathy. The systolic murmur reflects the haemodynamic situation with amyl nitrite, phenylephrine, and isoprenaline. Pressure measurements in left ventricle and femoral artery. Simultaneous external phonocardiogram shown in lower channel.

Squatting provides a simple bedside method of acutely increasing venous return, effective filling pressure of the heart, stroke output, and systemic arterial pressure (Sharpey-Schafer, 1956). We have therefore studied the effect of this manoeuvre on the systolic murmur in 11 patients with hypertrophic obstructive cardiomyopathy, and report the results in this paper. This effect has been compared with that from eight patients who have fixed valvar aortic stenosis and five patients with mitral incompetence, as the murmur in these cases may resemble that of hypertrophic obstructive cardiomyopathy. In addition, to help us in assessment of the mechanism of squatting we studied the effect of this procedure on the murmur of pulmonary stenosis.

Patients and Methods

In 11 patients the clinical diagnosis of hypertrophic obstructive cardiomyopathy was confirmed by cardiac catheterization cineangiocardiography, and the dynamic response to manipulation of the circulation by drugs affecting the severity of the left ventricular obstruction (Braunwald *et al.*, 1964a). The peak systolic pressure gradient between the inflow and outflow tracts of the right ventricle (intraventricular gradient) was measured. Mitral incompetence was assessed on cineangiocardiography. The clinical and haemodynamic features in each patient are given in Table I. In one patient (Case 10) the diagnosis was made on clinical grounds and by the typical response of the murmur to vasoactive drugs (Nellen *et al.*, 1965). Auscultation and phonocardiography were performed with the patient in the standing and squatting position, and the intensity and length of the systolic murmur was noted. Phonocardiograms were recorded on an Elema Mingograph 4 channel recorder (moving magnet ink jet galvanometers). Systemic arterial pressure was measured simultaneously with a cuff sphygmomanometer in both positions.

Squatting had to be prompt to achieve the optimum results. The patient was told to hold the edge of the examining couch while squatting. The stethoscope or phonocardiograph microphone was applied to the chest at the site of maximum intensity of the murmur, and the investigator then squatted rapidly and promptly with the patient, listening to the intensity of the murmur during held expiration. Prolonged breath-holding was avoided.

Eight patients with discrete valvar aortic stenosis and without mitral valve disease were studied for comparison of the effect of squatting on the systolic murmur. The clinical details of these cases and the results of cardiac catheterization and cineangiocardiography are given in Table II. The diagnosis has been confirmed at operation. Five cases with rheumatic mitral incompetence were diagnosed clinically by accepted criteria and the effect of squatting on the systolic murmur was also studied. Three cases of moderate pulmonary stenosis proved by catheterization were also investigated.

* From the Cardiac Clinic, Department of Medicine, University of Cape Town, and the Cardiovascular-Pulmonary Research Group, supported in the Department of Medicine by the Council for Scientific and Industrial Research.

Results

There was a rise in arterial and pulse pressure on squatting in each patient with hypertrophic obstructive cardiomyopathy. After 5–10 beats bradycardia occurred. The systolic murmur was promptly abolished in two and shortened and softened markedly in intensity in seven of the patients (Table I, Fig 2). In Case 10 the systolic murmur softened slightly—this patient was on a full dose of propranolol. In Case 11 the response was variable. The first heart sound usually softened and broadened. The second heart sound was unaltered or increased slightly in intensity. A fourth heart sound was recorded in five patients while standing. In three it moved towards the first sound, while in the other two there was little change in relation to the first sound on squatting. In no case did the murmur intensify.

In our studies of valvar aortic stenosis we found a similar increase in blood pressure and bradycardia, but the systolic murmur increased in intensity and length in six of the eight patients (Table II, Fig. 3). In the other two the change was insignificant. These two latter patients had poor left ventricular function as assessed by an elevated end-diastolic pressure in the left ventricle, left ventricular pulsus alternans, and an enlarged ventricle contracting poorly at cineangiocardiography.

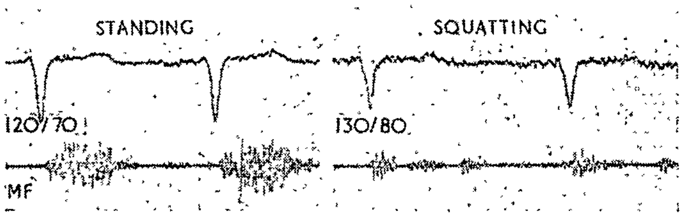

Fig. 2.—Case 3. Hypertrophic obstructive cardiomyopathy. Phonocardiogram (M.F.=medium frequency) taken medial to the apex. The systolic murmur is virtually abolished on squatting. (Lead V, of the electrocardiogram is indicated in the top tracing. Each large square on the record indicates 0.05 second.)

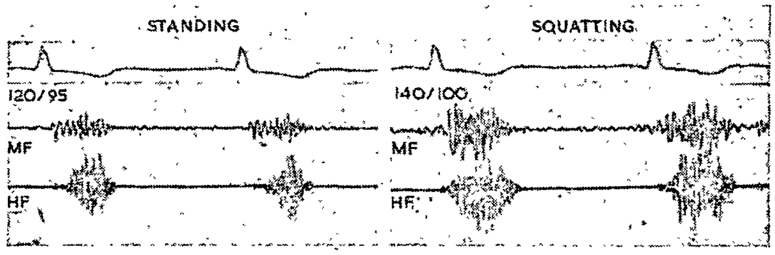

Fig. 3.—Case V. Valvar aortic stenosis. Phonocardiogram taken at the aortic area. The systolic murmur increases in intensity on squatting. (Upper tracing shows lead I of the electrocardiogram. M.F.=medium frequency; H.F.=high-frequency phonocardiogram.)

In five patients with rheumatic mitral incompetence the systolic murmur increased definitely but slightly on squatting. The third heart sound and mid-diastolic flow murmur also increased in intensity (Fig. 4). In three cases the systolic murmur of pulmonary stenosis intensified appreciably on squatting (Fig. 5).

Discussion

It has been shown (Sharpey-Schafer, 1956) that when normal subjects squat arterial mean pressure increases. The increase is greatest after a few seconds; thereafter mean pressure falls and eventually stabilizes at a level higher than the standing or sitting level. This we have confirmed (Fig. 6). The immediate rise in arterial pressure is believed to have two causes, the major factor being an increase in stroke output due to an increase in effective cardiac filling pressure, which in turn is due to squeezing blood out of the veins of the legs. The second factor, a minor one, is a small increase in peripheral arterial resistance due to the hydrostatic effect of the posture change and kinking of the femoral arteries. After a few seconds mean arterial pressure falls slightly owing to peripheral dilatation and stabilizes at a new level which is still higher than the control value. Bradycardia also occurs. This is a delayed baroceptor response. The slowing of the heart rate occurs at the highest blood pressure levels, but the changes in mean pressure and pulse pressure are still present if no rate changes occur, as in thyrotoxicosis or after atropine (Sharpey-Schafer, 1956). Squatting is thus an excellent procedure for increasing the effective filling pressure of the heart acutely; it is the converse of the Valsalva manœuvre (Sharpey-Schafer, 1955, 1956). This has been confirmed by Brotmacher (1957a, 1957b), who also demonstrated an increase in right atrial and pulmonary capillary wedge pressure when patients squat in the lying position. However, simultaneous oesophageal pressure was not measured in his cases.

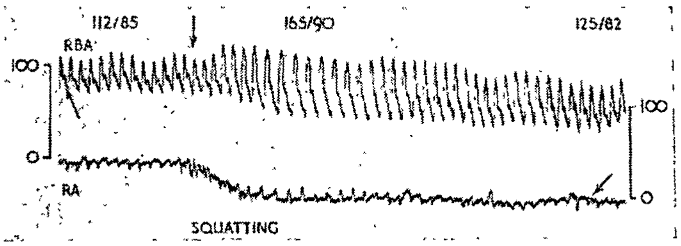

Fig. 6.—Effect of squatting on the arterial and right atrial pressure of a subject with mild pulmonary stenosis. Right atrial pressure increases very slightly on squatting. Mean arterial and pulse pressure increase, but there is a later fall and bradycardia from the baroceptor response; pulse and mean pressure are still greater than control values. (Zero level taken at the sternal angle in each position. Left-hand scale shows pressures in mm.Hg while standing and right-hand scale shows pressures on squatting.)

Similar studies by O'Donnell and McIlroy (1959) confirm Sharpey-Schafer's findings. They also showed that when subjects squat in a swimming-pool, so that the effect of gravity is removed, the haemodynamic response does not occur. A sudden increase in venous return and effective cardiac filling pressure would appear to be the cause of the increase in intensity of the systolic murmur in our cases of pulmonary stenosis. Increased peripheral resistance would not be a factor here. Our findings

in hypertrophic obstructive cardiomyopathy can similarly be explained by an increase in venous return which increases left ventricular filling and end-diastolic volume—an effect similar to a rapid infusion of blood or fluid or tilting the patient into a head-down position (Braunwald *et al.*, 1964a ; Shah *et al.*, 1965a ; Mason *et al.*, 1966).

With a larger intraventricular volume, the gradient lessens so that the stroke volume and mean arterial pressure increase. Though " contractility " may be enhanced initially, this is overcome by the increase in ventricular dimensions which reduces the degree of obstruction. An additional factor could be the baroceptor response to the raised arterial pressure and peripheral resistance leading to bradycardia and reduction of left ventricular contractility—a negative inotropic effect. A similar response to induced hypertension occurs during phenylephrine infusion, which diminishes the murmur of hypertrophic obstructive cardiomyopathy (Harrison *et al.*, 1964 ; Nellen *et al.*, 1965 ; Lewis *et al.*, 1965). These three factors—increased end-diastolic volume bradycardia, and reduced contractility—reduce the abnormal dynamic obstruction in the left ventricle. The systolic murmur, reflecting the intraventricular gradient, softens.

The murmur in hypertrophic obstructive cardiomyopathy can possibly be attributed to two other factors, obstruction to right ventricular outflow and mitral incompetence. In the present group of patients systolic pressure gradients within the cavity of the right ventricle were too small to account for the significant murmurs. Criley *et al.* (1965) suggested that the murmur is due to mitral incompetence from abnormally aligned papillary muscles in the small end-systolic cavity. We have assessed the degree of mitral incompetence from the cineangiocardiograms of our patients. In each patient reflux of dye into the left atrium was present, but this was often observed during diastole or during ventricular premature systoles, so that the degree of true incompetence was difficult to estimate. Our studies, in patients with hypertrophic obstructive cardiomyopathy, of the simultaneous response of the murmur and the pressure gradient within the left ventricle, recorded during manipulation of the circulation, indicate that the intensity of the murmur is related to the pressure gradient recorded (Nellen *et al.*, 1965). This suggests that the intraventricular obstruction is the most likely cause of the murmur, though mitral incompetence from abnormally aligned papillary muscles cannot be excluded.

The hypothesis of increased venous return can also explain the effect of squatting on the systolic murmur of aortic and pulmonary stenosis. This increases the stroke output of the left ventricle, more blood is ejected through a constant orifice per unit time, the velocity of flow is increased, and the murmur becomes louder and longer. If ventricular function is compromised, however, the stroke output increase does not occur (Thomas and Shillingford, 1965). A similar mechanism may apply to rheumatic mitral incompetence. The augmented venous return increases forward flow across the mitral valve, and hence the mid-diastolic flow murmur and third heart sound increase in intensity. The systolic murmur also increases slightly in loudness.

The softening of the murmur in squatting is thus a useful bedside test for recognizing hypertrophic obstructive cardiomyopathy. It increases significantly in intensity in the majority of patients with valvar aortic stenosis and slightly in mitral incompetence.

Summary

In 8 out of 11 patients with hypertrophic obstructive cardiomyopathy the systolic murmur softened and shortened in length with prompt squatting, while in two it was abolished.

In six out of eight patients with discrete valvar aortic stenosis there was an increase in intensity and duration of the systolic murmur on squatting. A similar but much less striking increase was observed in five subjects with mitral incompetence.

The response of the systolic murmur in hypertrophic obstructive cardiomyopathy to prompt squatting is a useful aid to bedside clinical diagnosis.

We wish to thank Dr. W. Beck, our colleagues in the cardiac clinic, and our laboratory staff for assistance with the catheterization procedures, and Dr. J. G. Burger, Superintendent of Groote

Schuur Hospital, for permission to publish. We acknowledge with thanks the continued financial support of the Council for Scientific and Industrial Research and the City Council of Cape Town.

Reduction of Clotting in Scribner Shunts by Long-term Anticoagulation

A. J. WING,* M.A., B.M., M.R.C.P. ; J. R. CURTIS,† M.B., B.S., M.R.C.P.
H. E. DE WARDENER,‡ M.B.E., M.D., F.R.C.P.

Brit. med. J., 1967, **3**, 143–145

Drukker *et al.* (1966) reported that 612 patients had been placed on regular dialysis treatment programmes in Europe by May 1966. For all these patients the Achilles heel of the treatment remains the arteriovenous shunt. The "life" of the shunts varies from centre to centre. Mean survival rates of between 2 and 14 months have been reported (Ramirez *et al.*, 1966 ; Pendras and Smith, 1966).

Shunt life is influenced by infection and clotting. There have been six infections in 16¼ patient-years' experience in this unit. The frequency of clotting incidents is much higher ; 59 during the same period (cf. Erickson *et al.*, 1966). This represents one clotting incident every 3.3 patient-months. At this rate, in a 10-bedded unit treating 30 patients 109 such incidents could be expected in the course of one year's operation.

When a shunt has clotted, declotting is necessary. Both events must be assumed to cause damage to the cannulated vessels. The clot causes anoxia to the intima, and the declotting procedure may traumatize the vessels. In addition it exposes the cannula site to the risks of infection. The risk of serious complications due to embolism appears to be slight. Clots are often released into the circulation at this procedure, and, despite the frequency with which it is carried out, there have been only isolated reports of collapse (Sokol, 1964) and of infected pulmonary emboli (Pendras and Erickson, 1965). Death has occurred on three occasions, each in a different unit, after declotting of arterial cannulae. Each patient became deeply unconscious after the procedure and some cerebral incident seems to have occurred. In our unit declotting is not carried out by the patients themselves and therefore they must come to the unit when they find that their shunt has clotted. A clotted shunt induces anxiety in the patient, for it is often the first of a series of clotting episodes and may be the signal that the cannula is coming to the end of its life. The significance of the loss of a cannula does not escape these patients. Clotting episodes place demands on the staff "on call," and the incidence of such episodes dictates in part the staff requirements for these units.

Long-term oral anticoagulation with warfarin sodium has been given to some of our patients. This communication reports the results so far.

Methods

Anticoagulants are not given to any patient until a clotting episode has occurred. Therefore, after their original cannulation the patients are included in the untreated group. When a clot occurs oral anticoagulants are begun. Warfarin sodium is used and the prothrombin time is kept at 1.5 times the control time. Prothrombin times are estimated by Quick's one-stage method with the use of lung thromboplastin (Geigy). A loading dose of 30 mg. is given and 48 hours later a maintenance dose is prescribed. The maintenance dose required by our patients is in the range of 3–12 mg. a day. During the first 48-hour period 5,000 units (50 mg.) of heparin is injected six-hourly by the patient himself into the shunt through a medicated sleeve described elsewhere (Evans, 1966). If further clotting occurs despite adequate anticoagulation, a venogram is obtained. If there is reason to suspect that the arterial cannula is at fault—that is, poor flows during dialysis without high pressure in the "venous" line—an arteriogram is also obtained. If angiography shows an obvious cause for clotting or poor flows, then surgical correction is necessary.

Because of this method of selection the treated group is made up of patients who have shown themselves to be at risk, and therefore includes patients whose cannulae have already been damaged by at least one clotting episode. The untreated group is made up of patients whose shunts have never clotted, and also includes those patients whose anticoagulants have been discontinued.

Results

Anticoagulation has reduced the frequency of clotting in the treated group.

Our total experience is now 195 patient-months. For 135 of these months anticoagulants have not been given, and during this time 52 clotting episodes have occurred. This represents a frequency of 4.6 clotting episodes per patient-year, or one every 2.6 patient-months. In the remaining 60 patient-months anticoagulants have been given and seven clotting episodes have occurred, a frequency of 1.4 clotting episodes per patient-year, or one every 8.6 patient-months.

Fig. 1 shows the difference between the incidence of clotting episodes in the treated and untreated groups.

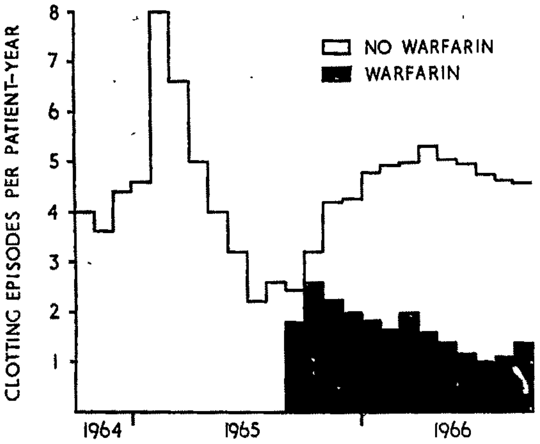

FIG. 1.—Number of clotting episodes that have occurred per patient-year is shown. The incidence of these episodes has been calculated month by month on a cumulative basis. Thus the incidence at any one month represents total experience up to that date. Open area=Number of episodes per patient-year in patients not receiving oral anticoagulation. Blackened area=Number of episodes per patient-year in patients treated with warfarin.

Case Histories

The following case histories illustrate the use and effect of anticoagulants in three patients (see Fig. 2).

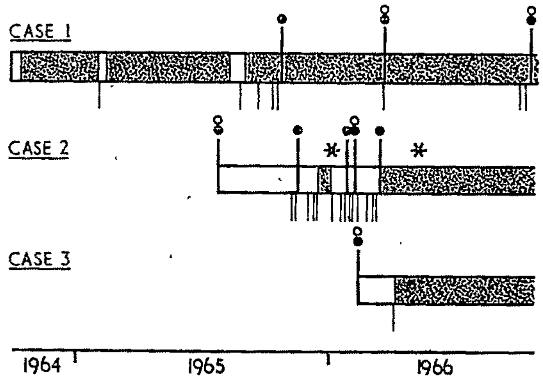

FIG. 2.—Each block represents the cannula history of individual patients, Cases 1, 2, and 3. For descriptions see text. Stippled area=Period for which warfarin was given. Each vertical bar below each block represents a clotting incident. Thick vertical bars extending above the blocks represent cannulation operations. Closed circle=New venous cannula. Open circle=New arterial cannula. Asterisks=Haemorrhagic complications occurring in Case 2.

Case 1.—A woman aged 24 with terminal renal failure due to chronic pyelonephritis had been on intermittent haemodialysis since 12 August 1964. Because of recurrent septicaemia, bilateral nephrectomy was carried out on 2 October 1964. Splenectomy was also done at this time in case it should later be possible to offer the patient renal transplantation. After operation clotting of the shunt occurred and the platelet count was raised for three months (375,000 to 850,000/cu. mm.). Warfarin was given. On two occasions, in February and August 1965, attempts were made to tail off the warfarin, but each time rebound clotting occurred. This patient is now on permanent anticoagulation. Recent clotting while adequately anticoagulated was associated with marked angiographic abnormalities.

Case 2.—A man aged 44 with terminal renal failure due to chronic pyelonephritis and gouty nephropathy had been on intermittent haemodialysis since 16 July 1965. After three months' good cannula function he damaged his shunt and eventually recannulation was necessary. There followed a rapid succession of clotting episodes, and four recannulations were carried out in three months. A first attempt at treatment with warfarin when the prothrombin time was kept at 2.0 times the control time resulted in a haematoma ; the drug was stopped and his shunt clotted. Anticoagulants were reintroduced in February 1966 and no further clotting has occurred. He developed a haemarthrosis in a previously gouty joint in April 1966 but there have been no further complications.

Case 3.—A woman aged 23 with terminal renal failure due to chronic pyelonephritis had been on intermittent haemodialysis since 15 January 1966. Previous transfusions, infusions, and cutdowns at another hospital had severely reduced the number of veins suitable for cannulation, and her first successful cannulation was in the left brachial artery and basilic vein. Clotting of the shunt occurred after six weeks. Fortunately, anticoagulation has so far prevented any further clotting. Considerable fibrin formation during dialysis has been noted in this patient.

Complications

There have been four haemorrhagic complications. Two spontaneous haematomas occurred in the treated group, and on both occasions the prothrombin time was 2.0 times the control time. One, in the neck, threatened respiratory obstruction. The haemarthrosis in one of Case 2's gouty joints required aspiration. One treated patient developed a haematoma in a cannulation wound.

Discussion

The risks of the use of anticoagulants are well documented (Hudson, 1965). They are those due to haemorrhage and those due to hypersensitivity. Of the four haemorrhagic complications in this unit two occurred when the prothrombin time was prolonged well above the 1.5 times the control which is now regarded as optimal. Should hepatitis develop, dosage requirements may change rapidly, and frequent estimations of the prothrombin time are indicated. Gastrointestinal haemorrhage and pericarditis are contraindications to the use of anticoagulants. Dangerous hypersensitivity reactions can be avoided by using warfarin as opposed to phenindione (Hollman and Wong, 1964).

Patients who clot their shunts repeatedly have, on average, a shorter shunt "life" (cf. Pendras and Smith, 1966). The use of warfarin in such patients has reduced the frequency of clotting and has prolonged the life of their shunts. We believe that the added risks are worth taking in those patients who are known to be at risk of clotting their shunts. Some patients do not have clotting problems. In our untreated group we have three patients totalling 2 years 10 months' experience who have never clotted their shunts. Erickson *et al.* (1966) have reported that cannulated haemodialysed patients have a higher level of blood-clotting factors than a random non-uraemic control group. They have also found that the level of clotting factors is higher in "clotters" than in "non-clotters." This work suggests that it may eventually be possible to predict which patients should receive anticoagulants.

There is a further difficulty in handling anticoagulants in these patients: once begun, they are difficult to withdraw. This has been attempted on six occasions in five patients, and on four of these occasions due care was taken to "tail off" the dosage. The other two occasions were regarded as serious haemorrhagic emergencies requiring abrupt cessation of anticoagulants. Four out of the six attempts to withdraw anticoagulants resulted in clotting of the shunts, and in three of these the site was lost within a fortnight. A further patient who discontinued his warfarin because of a misunderstanding promptly clotted his shunt.

Clotting in the shunts is due in part to blood-clotting factors, and because of this warfarin has reduced their frequency. Clotting may also be initiated if the patient is made hypotensive owing to excessive ultrafiltration during dialysis. There remain mechanical defects in the components of the shunt and structural defects in the cannulated vessels which may precipitate clotting. When repeated clotting of the shunt has occurred without hypotensive episodes and despite adequate anticoagulation, then a venogram and, if indicated, an arteriogram are obtained. Under these circumstances a structural defect in one or both vessels has always been demonstrable. Such abnormalities have included stenosis of the vessel near the cannula tip, malalignment, and aneurysmal dilatation (see Figs. 3–6). These radiographic appearances only serve to emphasize the extreme importance of careful surgery and expert cannula care. Attention to heparinization during dialysis is necessary to minimize fibrin formation, which may lead to deposition in the cannulated vein. Erickson *et al.* (1966) have observed one patient in whom such fibrin formation was a problem and who also suffered repeated clotting episodes. Warfarin abolished both.

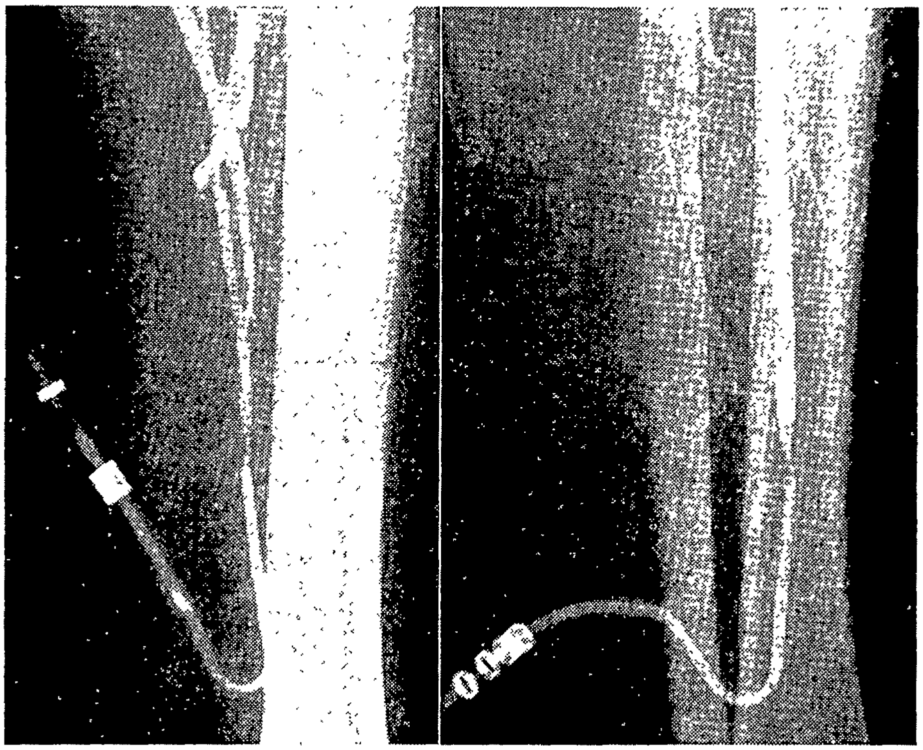

FIG. 3 FIG. 4

FIGS. 3 and 4.—Venograms showing stenotic lesions at cannulae tips. These are very commonly found. In both patients the cannula was successfully placed a little higher up the same vessel.

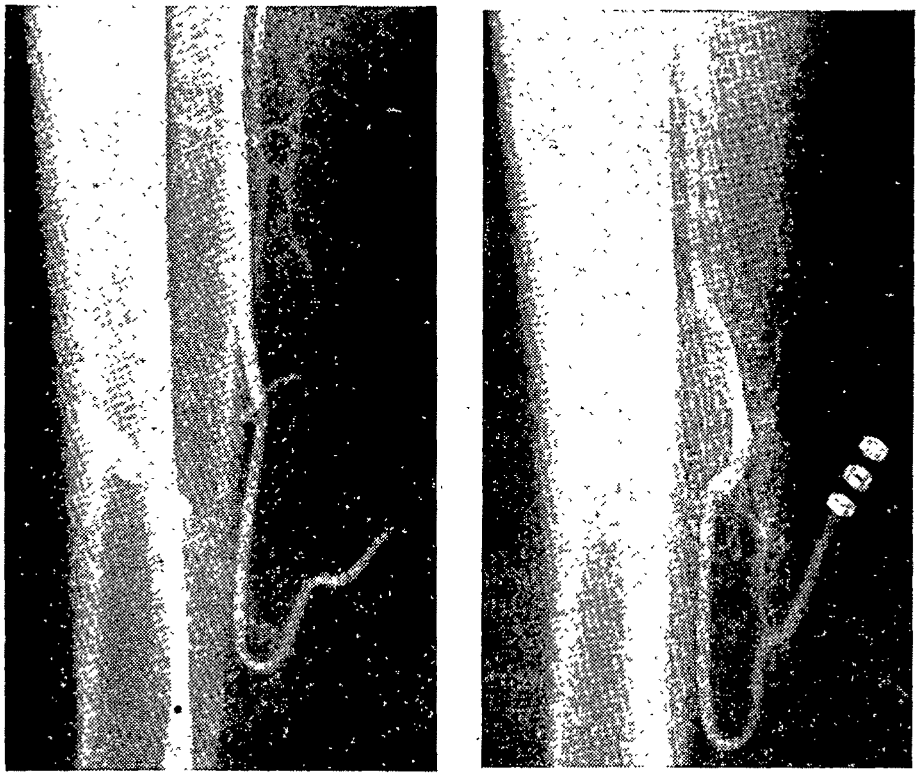

FIG. 5 FIG. 6

FIG. 5.—Arteriogram showing angulation at junction of Teflon tip and vessel. This gave rise to poor flows during dialysis, and eventually clotting occurred. FIG. 6.—Arteriogram showing an S-bend deformity of the artery. The cannula had been inserted incorrectly in relation to the tendon of flexor digitorum longus. Intermittent cessation of flow during dialysis occurred, and eventually the shunt clotted. Note the leash of small vessels. This shunt had previously been infected.

Summary

Oral anticoagulation with warfarin has been given to a selected group of patients being treated by intermittent haemodialysis. The group was composed of patients whose shunts were known to be at risk because of previous clotting episodes. Treatment has decreased the frequency of clotting episodes and has prolonged the "life" of the shunts in this group of patients. Any success with the use of anticoagulants should not be allowed to detract from emphasis on accurate cannula placement and good cannula care, and on avoidance of hypotensive episodes.

Diagnostic Paracentesis in the Acute Abdomen

W. N. W. BAKER,* M.B., B.S., F.R.C.S.; D. B. MACKIE,* M.B., M.CHIR., F.R.C.S.
J. F. NEWCOMBE,† M.CHIR., F.R.C.S.

Brit. med. J., 1967, 3, 146–149

Diagnostic paracentesis of the peritoneal cavity in abdominal emergencies has been practised in the United States for many years, but has never become popular in this country (Morris, 1966).

The first comprehensive study of the technique was carried out by Neuhof and Cohen (1926), who reported enthusiastically on its use as a diagnostic aid in the evaluation of closed abdominal injuries, acute pancreatitis, and primary pneumococcal or streptococcal peritonitis. Though no cases were reported in their paper, they also predicted a wider use for the test in the diagnosis of ruptured hollow viscera and bleeding ectopic pregnancies.

Later studies have confirmed these observations, especially in relation to blunt abdominal trauma (Thompson and Brown, 1954; Economy *et al.*, 1960). Williams and Zollinger (1959) reviewed 273 abdominal injuries, 80% of which were non-penetrating, and reported that needle paracentesis had proved accurate in 79% of these cases. They compared the relative diagnostic values of paracentesis and *x*-ray findings in the same series, and found that radiology was more valuable in injuries to kidney and bladder (where paracentesis is usually negative), but that paracentesis was far superior as a diagnostic aid in lacerations of liver, spleen, or pancreas.

Keith *et al.* (1950) stated that it is often a useful investigation in acute pancreatitis. They obtained fluid in 12 out of 15 consecutive cases, and in all of these the amylase levels were higher than those found in the serum. Moreover, the peritoneal fluid amylase remained high for two to three days after the serum levels had returned to normal. However, Moretz and Erickson (1954) warn that peritoneal fluid amylase is also raised in perforated peptic ulcer and intestinal strangulation, and care must be taken in interpreting this finding.

The accuracy of the procedure was investigated experimentally by Giacobine and Siler (1960). Their observations on dogs showed that there was a linear relation between the amount of fluid in the peritoneal cavity and the probability of obtaining a sample by needle paracentesis. The low rate of positive results with small amounts of fluid was shown radiologically to be due to pooling in the pelvis, paravertebral gutters, and subphrenic spaces.

Material and Methods

The cases were an unselected series of 101 patients admitted as acute abdominal emergencies to a general hospital. There were 50 males and 51 females in the series, with an age range from 6 to 89 years.

Technique

The standard procedure throughout this investigation was the four-quadrant tap advocated by Byrne (1956). Though most authors advocate the use of a spinal puncture needle, entirely satisfactory results were obtained with a 2-ml. or 5-ml. disposable syringe and No. 12 needle. Local anaesthetic was not routinely employed and asepsis was confined to socially clean hands and a spirit skin preparation.

The needle was inserted at the sites shown in the Diagram. Light intermittent suction was applied as the needle tip was moved about within the peritoneal cavity, seeking pockets of free fluid. This is necessary to obtain a sample when only a small quantity of fluid is present as a thin film beneath the parietal peritoneum.

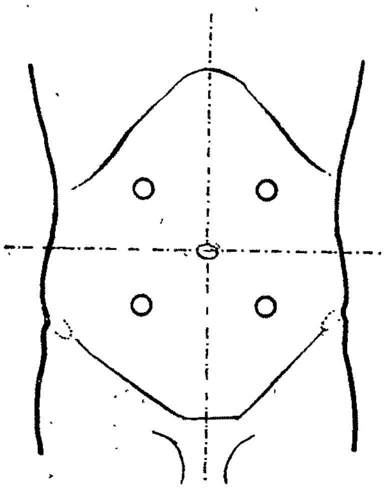

Diagram showing sites of puncture in the standard four-quadrant paracentesis

Occasionally a very small quantity (less than 0.5 ml.) of clear peritoneal fluid is obtained in the absence of intra-abdominal morbidity. When a larger quantity than this is obtained there is nearly always an underlying cause. For this reason we have regarded a paracentesis as "positive" if clear fluid in excess of 0.5 ml. has been obtained. If the fluid is obviously pathological—for example, pus—then the paracentesis is "positive" regardless of its volume.

The necessity of carrying out a full four-quadrant technique before pronouncing a paracentesis to be negative was demonstrated on several occasions in this series. In one case pus was obtained only from the *right upper* quadrant though the lesion was a perforated diverticulum of the sigmoid colon in the *left lower* quadrant. This also shows that the method gives no indication of the probable site of the primary lesion.

Safety of the Technique

The objection to the technique most often raised has been on the grounds of safety. This point has been investigated experimentally in dogs by Moretz and Erickson (1954). When isolated segments of intestine were deliberately punctured and subsequently inflated no leakage occurred until a pressure of 260 mm. Hg was reached. Even in complete intestinal obstruction the intraluminal pressure seldom rises above 15 mm. Hg in the small bowel and 20 mm. Hg in the large bowel

† Consultant Surgeon, Central Middlesex Hospital, London.

(Wangensteen, 1942). Leakage from accidental puncture is therefore a very small hazard. Nevertheless, in the presence of distended bowel the risk must be increased, and we believe that paracentesis should not be done in these circumstances.

No complication was recorded in any of the 101 cases reported, though visceral puncture did occur. The gall-bladder, the stomach, and the colon were each penetrated at some time. In those cases undergoing subsequent laparotomy no evidence of haemorrhage or peritoneal soiling was found. This confirms the findings of all previous authors. Indeed, the only complication recorded in the literature is of a haematoma of the rectus sheath after a paramedian tap (Drapanas and McDonald, 1961).

Interpretation of a Positive Paracentesis

Frank Blood.—The withdrawal of pure blood that fails to clot on standing can only mean that a significant intraperitoneal haemorrhage has occurred. Accidental puncture of a blood vessel does occur but can readily be distinguished by the fact that blood from this source clots within a few minutes.

Serosanguineous Fluid.—This type of exudate has been reported in a number of situations, including strangulated hernia (Hill *et al.*, 1942) and acute pancreatitis (Keith *et al.*, 1950). In the present series it was found in only two cases. One was a traumatic rupture of the kidney with a retroperitoneal haematoma, in which the paracentesis did not contribute towards the diagnosis. The other was a case of acute cholecystitis, described in detail below (Case 1).

Purulent Fluid.—This may vary from the offensive frank pus obtained from a perforated appendix or diverticulum of the colon to the thin turbid fluid associated with localized inflammatory disease. The latter contains numerous polymorphs on smearing the centrifuged deposit (see Case 1 below).

Bile-stained Fluid.—This type of fluid is characteristic of a perforated ulcer, and in the present series was the most common finding on paracentesis. Usually the fluid is turbid and contains food particles. A most important observation in our series was that the fluid was *never* acid when tested with ordinary litmus paper. Even when the sample was obtained very soon after the onset of acute symptoms the fluid was either neutral or alkaline. On one occasion the gall bladder was accidentally punctured in the right hypochondrium, yielding pure bile. This was correctly interpreted and no harm resulted.

Faecal.—When the intestine is accidentally punctured it is usually easy to recognize this by naked-eye inspection of the material aspirated. In cases of doubt, microscopy reveals a mixture of intestinal bacteria and debris with no evidence of polymorphs. No complications have resulted from this accident and there is no reason why the paracentesis should not be attempted with a fresh needle and syringe at a different site in the same quadrant.

Misinterpretation of a Positive Paracentesis

On two occasions a positive paracentesis was misinterpreted, and since each case illustrates a useful point they are described in detail.

Case 1.—An 87-year-old woman was admitted to hospital as an emergency with a history of severe upper abdominal pain of sudden onset. Examination revealed tenderness and guarding in the upper abdomen. A plain *x*-ray film showed no gas under the diaphragm. The serum amylase was less than 500 Somogyi units. On abdominal paracentesis a small quantity of serosanguineous fluid was obtained from the right hypochondrium. Microscopy of the centrifuged deposit showed numerous polymorphs, indicating the presence of an inflammatory lesion. Despite the nature of this fluid a clinical diagnosis of perforated peptic ulcer was made. At laparotomy the gall bladder was found to be acutely inflamed, and immediately surrounding it was a collection of free fluid identical to the aspirated sample. The stomach and duodenum were entirely normal.

Comment.—This is one of the two cases in which a positive paracentesis was obtained in the presence of local inflammatory disease. The point demonstrated is that where pathological fluid is obtained the diagnosis must be consistent with its type. Here the fluid was quite uncharacteristic of a perforated peptic ulcer, and this diagnosis should not have been made.

Case 2.—A man aged 62 was admitted to hospital with a history of upper abdominal pain for the preceding three days which had become much more severe that day. On admission there was clinical and radiographic evidence of bronchopneumonia. He was a known chronic bronchitic and was under treatment for recurrent episodes of congestive cardiac failure. However, there was also evidence of a perforated viscus, with marked tenderness over the whole abdomen and guarding in the epigastrium. Bowel sounds were absent. This diagnosis seemed confirmed when, on abdominal paracentesis, bile-stained fluid with food particles was obtained from the *left iliac fossa.* The *p*H of the fluid was not tested. All attempts to pass a Ryle tube failed. Since his condition was rapidly deteriorating it was decided to proceed with laparotomy. At operation no free fluid was found in the peritoneal cavity. The stomach was full of fluid and extended right down to the left iliac fossa. On its anterior surface was a puncture mark indicating that the attempted paracentesis had in fact withdrawn gastric contents. The patient died shortly after operation. At necropsy no cause was found for his abdominal symptoms. The only positive finding was an organizing bronchopneumonia, and it must be presumed that this was responsible for his entire clinical picture.

Comment.—This case has revealed a possible source of error that has not hitherto been reported. Two omissions probably account for the misinterpretation of the paracentesis. Firstly, if the *p*H of the fluid had been tested it would very probably have been acid. As stated above, fluid from a perforated peptic ulcer appears invariably to be either neutral or alkaline. Secondly, it proved impossible to pass a Ryle tube preoperatively. Had this been achieved, the large aspirate would have been noted and a repeat paracentesis would have proved negative. It therefore seems desirable always to test the *p*H of the fluid obtained from cases of suspected perforation. It would also seem more reliable to perform the paracentesis *after* gastric aspiration. However, this must be a very uncommon source of error.

Interpretation of a Negative Paracentesis

It cannot be too strongly emphasized that *a negative paracentesis has no positive significance.* If operation is indicated on clinical grounds, then, whatever the diagnosis may be, the fact that no fluid has been obtained from the peritoneal cavity must be completely disregarded.

If there is no clear indication for immediate surgery on clinical grounds, a negative paracentesis may help to justify continuation of conservative treatment, but it should be given no significance in arriving at a diagnosis.

Results

Of the 101 cases in which diagnostic paracentesis was performed, an acute abdominal condition was demonstrated at laparotomy or necropsy in 64. Of four further cases presenting with severe abdominal pain, two were subsequently shown to have malignant disease, one had a coronary thrombosis, and one had tuberculosis of the urinary tract. Ascitic fluid was obtained from the former two cases; in the latter two the paracentesis was negative.

There was therefore a total of 68 cases in which a firm diagnosis was made. In this group a positive paracentesis was obtained in 33 and a negative result in 35. In Table I these results are analysed according to final diagnosis.

From these data a clear pattern emerges. Diagnostic paracentesis was found to yield accurate positive information in 22 out of 28 cases of visceral perforation. No attempt was made to compare the relative accuracy of this technique with that of diagnostic radiography, but it is unlikely that the latter method would have proved significantly better.

TABLE I.—*Abdominal Emergencies With Known Diagnosis*

	Paracenteses		
	No.	Positive	Negative
Group I. Visceral Perforations			
Stomach and duodenum	19	14	5
Small bowel	2	2	0
Colon and appendix	7	6	1
Total	28	22 (79%)	6
Group II. Intraperitoneal Haemorrhage			
Ectopic	2	2	0
Leaking arterial anastomosis	2	2	0
Ruptured spleen	3	2	1
Total	7	6 (86%)	1
Group III. Localized Intra-abdominal Inflammatory Disease			
Acute appendicitis	11	0	11
Cholecystitis	5	1	4
Salpingitis	3	0	3
Pancreatitis	2	0	2
Diverticulitis	1	0	1
Acute duodenal ulcer	1	0	1
Primary peritonitis	1	1	0
Liver abscess	1	0	1
Total	25	2 (8%)	23
Group IV. Miscellaneous			
Intestinal obstruction	4	1	3
Malignant disease	2	2	0
Urinary tract tuberculosis	1	0	1
Coronary thrombosis	1	0	1
Total	8	3	5
Grand total	68	33	35

In cases of intraperitoneal haemorrhage blood was obtained in six out of seven paracenteses, a comparable degree of accuracy with the large series of such cases reported by Williams and Zollinger (1959).

In direct contrast to these findings are the results for localized inflammatory disease. Here it is quite clear that diagnostic paracentesis is most unlikely to give useful information. In only two cases out of 25 was a positive paracentesis obtained. One was the case of acute cholecystitis described above (Case 1). The other was a case of peritonitis, for which no cause was found at laparotomy and which was therefore classified as a primary peritonitis.

Only two cases of acute pancreatitis were encountered in this series, and no fluid was obtained from either of them.

Of the four patients with intestinal obstruction only one yielded a positive result. As stated above, the technique is not recommended for florid cases of obstruction, and in this series it was used only when the diagnosis was not clear. It may have a place in the diagnosis of intestinal strangulation (Hill *et al.*, 1942), but the one such case in this series produced a negative result. At laparotomy there was a small amount of faeculent blood-stained fluid in the peritoneal cavity, but paracentesis had failed to detect it.

A recurrent problem in which the test may prove an outstanding aid to diagnosis is that of the postoperative patient who develops intra-abdominal complications. A recent anaesthetic, followed by the customary analgesia, makes the interpretation of physical signs notoriously difficult in these cases. Brief summaries of two such cases are given.

Case 3.—A 57-year-old man presented with an 18-month history of severe intermittent claudication of his left buttock and thigh after walking 25 yards (23 metres). An aortogram revealed atherosclerotic occlusion at the aortic bifurcation. He underwent an aorto-iliac thrombendarterectomy on 21 February 1966. Two hours after the end of the operation he had a cardiac arrest in the ward. He was resuscitated from this successfully, but 15 minutes later his blood pressure again fell rapidly. At the time it was not clear whether this was due to myocardial damage or to bleeding from the aortic suture line. A diagnostic paracentesis was performed and non-clotting blood obtained from the right lower quadrant. On this evidence he was immediately returned to the theatre and the wound reopened. The diagnosis of leaking aortic suture line was confirmed (the peritoneal cavity containing some 2 litres of blood). Unfortunately the heart arrested again on the table before the bleeding could be properly controlled, and though it was restarted by open cardiac massage the patient did not survive.

Case 4.—A 52-year-old woman was admitted to hospital with a diagnosis of coronary thrombosis, and while on treatment suddenly developed the signs of an embolus at the aortic bifurcation. On 1 June 1966 an emergency aorto-iliac and bilateral femoral thrombectomy was performed. Her immediate postoperative condition was satisfactory, with a rapid return of the peripheral pulses in both legs. However, 12 hours later she began to deteriorate rapidly with signs of peripheral circulatory failure. It was thought likely that leakage had occurred from her arterial suture line, so a diagnostic paracentesis was performed. This produced heavily bloodstained fluid with a faecal odour from the right lower quadrant. She was taken back to the theatre and re-explored. At operation there was approximately 1 litre of blood in the peritoneal cavity, presumed to be due to a leak from the aortic suture line, though this was dry when exposed. However, the most significant finding was infarction of the colon, which accounted for the faeculent odour of the aspirate and which was undoubtedly the cause of the rapid deterioration in her condition. The inferior mesenteric artery was pulseless. An emergency colectomy was performed but the patient died a few hours later.

Comment.—Though unfortunately both these patients died, they do nevertheless illustrate that valuable information can be obtained from a diagnostic paracentesis in the early postoperative period when the critical decision has to be made whether or not to reoperate. Almost certainly in both these cases the correct decision would have been made eventually, but where speed of decision was essential no other single clinical investigation could have supplied the information so swiftly or so accurately.

Undiagnosed Abdominal Pain

There remains to be considered the group of 33 patients who were admitted with acute abdominal pain for which no cause was firmly established. They are analysed in Table II, and, broadly speaking, fall into two categories: (A) those with suspected acute intra-abdominal inflammatory disease; and (B) those with suspected intra-abdominal bleeding or a perforated viscus following blunt abdominal trauma.

TABLE II.—*Undiagnosed Abdominal Conditions*

	Paracenteses		
	No.	Pos.	Neg.
Group A, suspected inflammatory disease	23	1	22
„ B, suspected bleeding or ruptured viscus (a) Spleen	8	0	8
(b) Bladder	2	0	2
Total	33	1	32

Of the 23 cases in group A the one positive paracentesis was obtained in a woman of 83 admitted with a clinical diagnosis of acute cholecystitis. Turbid fluid containing polymorphs was obtained from the right hypochondrium, which supported this diagnosis. Though the patient recovered on conservative treatment she was not regarded as a candidate for subsequent surgery, and the diagnosis was not confirmed radiologically.

Negative paracenteses were obtained in all 10 cases in group B. Only one of these underwent operation. This was for a suspected traumatic rupture of the bladder, but laparotomy revealed only a retroperitoneal haematoma. The remaining nine cases all recovered on conservative treatment.

Discussion

This investigation has served to clarify the place of paracentesis in a variety of acute abdominal conditions.

In the first place the findings confirm the opinion of previous authors that the test is both simple and completely safe. We have also confirmed that a full four-quadrant technique is essential before a paracentesis can be regarded as negative.

Though the number of cases is small, the most accurate results have been obtained in suspected intraperitoneal haemorrhage. Since there is experimental evidence (Giacobine and Siler, 1960) that a volume of 500 ml. of free fluid in the peritoneal cavity will give a 78% positive paracentesis rate, the method is likely to be more sensitive and accurate than any other single diagnostic aid. We strongly recommend its use in all cases of blunt abdominal trauma, and particularly when the clinical picture is confused by the presence of other injuries.

In visceral perforations again a high yield of positive results was obtained, but in evaluating the method in this situation there are other factors to consider. Firstly, the clinical picture is usually much clearer than in intra-abdominal haemorrhage, so that in many cases ancillary aids to diagnosis are not required. Secondly, another simple diagnostic method—the plain erect and supine abdominal *x*-ray films—is available and also gives a high yield of positive results.

In cases where the clinician is in no doubt about the diagnosis, neither method is necessary and laparotomy need not be delayed. There are, however, many situations in which varying degrees of doubt exist regarding whether or not perforation has taken place. In these cases has paracentesis any advantage over *x*-ray examination as a method of diagnosis ?

In favour of paracentesis we can say: (*a*) it is a test that can be performed immediately by the clinician at the bedside ; (*b*) it disturbs the patient far less than the manipulations required to obtain a satisfactory view of the erect abdomen ; (*c*) it is an extremely useful test for hospitals lacking a 24-hour radiological service ; and (*d*) it gives a yield of positive information which is at least comparable to that of *x*-ray techniques.

By contrast, in localized inflammatory disease the yield of positive information is so low that abdominal paracentesis cannot be recommended as a useful diagnostic aid. The only exception to this may be in helping to differentiate between a localized inflammation and a perforated viscus, where the history and examination are equivocal.

Finally, we must repeat the warning, as have many previous authors, that a *negative paracentesis has no significance.* Serious underlying conditions may be present despite a negative tap. Our figures demonstrate that this is especially likely in localized inflammatory disease, but it is true also in intraperitoneal haemorrhage and visceral perforations.

In conclusion, therefore, we believe that diagnostic paracentesis is a useful procedure in the evaluation of patients with suspected intraperitoneal haemorrhage and visceral perforation, but has little place in the diagnosis of localized intra-abdominal inflammatory disease.

Summary

The value of diagnostic paracentesis has been studied in 101 patients admitted as cases of acute abdominal emergency.

The technique has been shown to be both simple and safe. Though visceral puncture may occasionally occur, no complications have resulted.

Analysis of the results shows that a high yield (approximately 80%) of positive paracenteses can be expected in cases of intraperitoneal haemorrhage and perforated viscus. Conversely, a very low yield (less than 10%) was obtained in localized inflammatory disease.

The test is strongly recommended as routine in all cases of blunt abdominal trauma. It is also extremely useful in the early diagnosis of complications after abdominal surgery.

In visceral perforation the method offers a useful alternative to radiological diagnosis, and in certain respects is to be preferred.

Our thanks are due to Mr. J. W. P. Gummer for permitting us to include his patients in this study.

Treatment of Stress Incontinence by Maximum Perineal Electrical Stimulation

THOMAS MOORE,* M.D., M.S., F.R.C.S. ; PHILIP F. SCHOFIELD,† M.D., F.R.C.S.

Brit. med. J., 1967, 3, 150–151

Stress incontinence is one of the commonest symptoms to occur in the female. It has been estimated that more than 50% of nulliparous women have incontinence when severe stress is placed on the bladder (Nemir and Middleton, 1954). However, it is only when incontinence occurs on minor stress such as coughing or walking that the patient presents for advice.

Jeffcoate (1961) suggests that the main factor is the loss of the normal urethrovesical angle. Lapides *et al.* (1960a, 1960b) felt that the principal defect was shortening of the urethra due to absence of the lengthening effect of the pelvic floor muscles. These views are probably not divergent, as descent of the bladder base can produce both the alteration in the angle and urethral shortening. Vincent (1959, 1966) has shown how mechanical raising of the perineum by an external appliance can tighten the pelvic floor muscles and the urethra and abolish incontinence.

On theoretical grounds incontinence occurs from either the uncontrolled action of the bladder muscle or some defect in the normal resistance of the bladder-neck and urethra. Beck, Hsu, and Maughan (1965) showed low urethral pressures due to general laxity of the urethral musculature in stress incontinence.

Perineal muscle exercises and faradism are known to bring improvement in this type of case (Jones, 1963). Some years ago one of us (T. M.) carried out studies of the electrical activity of the urethral muscles in all types of incontinent females by placing needle electrodes along the urethral wall. In one patient, in whom the anaesthesia was not deep enough, reflex contraction of the whole pelvic floor muscles followed introduction of the electrodes. Afterwards the patient's incontinence was mysteriously much improved.

Because of this observation it was decided to treat incontinent females empirically by causing maximal contractions of the pelvic floor muscles by electrical stimulation, under anaesthesia.

Method

Ten patients, who had only cystoscopy and measurement of urethral length, were used as a control group. Eighteen patients with marked stress incontinence had cystoscopy, measurement of urethral length, and maximal perineal faradism (see Table). Ten patients with other types of incontinence, four cases of enuresis, three cases of urge incontinence, and three cases with gross structural changes in the urethra had the same examination and treatment.

The faradism was given by electrodes—a mobile one placed over the perineal body and a stationary one under the sacrum—by a selective treatment unit (Stanley Cox Ltd.). The faradic surge consisted of pulses of one millisecond and the whole surge lasted for two to three seconds. There was then a pause of two to three seconds before a further faradic surge. The intensity of the stimulation was increased until all the voluntary musculature gave a maximal contraction. From four to six maximal tetanic contractions were produced in each patient.

Classification of the results is difficult, but these have all been assessed after treatment by one of us (P. F. S.) and the patients who have no further stress incontinence in the first three months after treatment are placed in the "cured" category. It was accepted that patients may be classified as improved if they stated that the treatment was worth while, that the amount of protective pads worn per day was fewer than three, and if the assessor was convinced from the history and examination of the urethra when the patient was straining that there was improvement. All other patients were classified in the failure group.

Results

No other type of incontinence showed any improvement. One of the group of 10 patients who had only cystoscopy showed improvement but relapsed at four months. Ten out of 18 patients with stress incontinence were either considerably or completely relieved of their symptoms (see Table).

Investigation and Results of Treatment of Stress Incontinence

Age	Cystoscopy	Urethral Length in cm.	Neurological Signs	Result
41	Cystitis cystica	2·1	—	Failure
46	None	2·7	—	Cured
46	,,	2·0	—	Improved
50	,,	1·8	—	Failure
31	,,	2·3	—	,,
43	Trabeculation	2·2	—	Cured
55	None	—	—	Failure
52	Trabeculation	2·3	—	Improved
38	None	2·0	—	Cured
27	,,	3·5	—	,,
32	,,	1·9	—	,,
21	,,	2·5	—	Failure
26	,,	2·4	—	,,
38	,,	1·9	—	Improved
37	,,	1·6	—	Failure
26	,,	—	—	Improved
47	,,	2·5	—	Failure
44	,,	2·1	—	Cured

Four patients relapsed partially by six months, but two of them responded to further faradism under general anaesthesia and the other two did not feel their symptoms were severe enough to require treatment. Six patients have remained much relieved for one year.

Six of the eight patients who failed to respond were treated by Lapides's (1961) operation ; five of these were relieved of all symptoms, but one still had stress incontinence.

Discussion

Urinary control is a learned function, and, as with any learned lesson, there are various degrees of success. Urinary control in the normal female is often not perfect ; in fact, more than 50% of normal nulliparous females have slight incontinence on occasions of severe and sudden stress (Nemir and Middleton, 1954). More gross degrees of loss of control are only too distressingly common.

In the past, treatment has taken two main lines: (1) operation to alter the orientation of the bladder-neck and urethra or to

† Senior Surgical Registrar, Department of Urology, Manchester Royal Infirmary. Present address: Cleveland Clinic, Ohio, U.S.A.

elongate the urethra ; and (2) physical treatment by exercises and electrical stimulation to improve the perineal musculature.

Electrical stimulation to the perineum has been carried out for many years in the treatment of minor stress incontinence, and electrical devices have recently been used to treat incontinence of both urine and faeces (Caldwell, 1963 ; Hopkinson and Lightwood, 1966 ; Caldwell, Flack, and Broad, 1965). Caldwell *et al.* (1965) delivered a square wave pulse to the urinary sphincter in a patient with urinary incontinence after spinal injury, with gratifying results. It is interesting to note that some patients recover sufficient sphincter power to discard the electrical apparatus in time.

The cause of stress incontinence is an imbalance between the pressure in the bladder and the resistance in the urethra. Normally all conditions of stress causing an increase of intravesical pressure are accompanied by a corresponding increase in the urethral resistance. The mechanism of this reaction is that increase of abdominal muscle tone is always accompanied by an increase in the tone of the pelvic floor muscles and a consequent elongation of the urethra by the contraction of the pubococcygeus muscle. Lapides *et al.* (1960a, 1960b) and Lapides (1961) stated that in the female a urethral length of 3 cm. was necessary for continence. Personal observations have confirmed that in most cases of stress incontinence the urethra is less than 3 cm. long and have also shown that in cases of stress incontinence standing causes a shortening of the urethra. This is due to loss of tone of the pelvic floor muscles, which do not contract in response to the increased intra-abdominal pressure and elongate the urethra. In normal females without stress incontinence standing causes an increase in the length of the urethra by 1 cm. or more. We have also shown that during maximal stimulation under general anaesthesia the urethra lengthens by 1 cm. or more, to return to its original length when the electrical stimulation is stopped.

We presume that when the anaesthetic has worn off the tone of the perineal floor muscles returns and is greater than before treatment. The change in the length of the urethra and possibly some narrowing of the urethral lumen associated with the return of tone of the perineal muscles increases the urethral resistance, in accordance with Laplace's law.

In successful cases we have not remeasured the urethra to confirm its elongation because of a fear of causing further symptoms. The success of the treatment we presume is because maximum perineal contraction of the perineal muscles causes a maximum physiological rehabilitative response and is better than long-continued intermittent faradism or voluntary exercises. The improvement that follows the stress incontinence occurring directly after childbirth by pelvic floor muscle exercises is well known. In our view it is likely that such patients would recover more quickly if treated with maximal perineal electrical stimulation.

It will be noted from the Table that improvement in stress incontinence occurred in some cases in which the urethra was much shorter than 3 cm., though it was more likely to occur in those cases in which the urethra was more than 2 cm. long. The fact that such results can be obtained with very short urethrae shows how effective the method can be.

The encouraging results in which 6 (33%) out of 18 patients with stress incontinence have been completely relieved of symptoms and a further 4 (22%) considerably improved merit further studies. We are so convinced of the efficiency of the method and by its safety and simplicity that we now tend to try it in any case of urinary incontinence. In some cases of neurogenic bladder it might well have a most beneficial effect in restoring better power to muscles not completely paralysed by the nervous disease. It should, however, be tried in all cases of true stress incontinence before operation is advised, particularly in those patients with a short history and a urethra shorter than normal in the standing position only by 1 cm. or less.

Summary

Stress incontinence of urine in the female is usually due to loss of tone of the pelvic floor muscles with consequent shortening of the urethra. In the erect posture the urethra must be at least 3 cm. long.

Cases were treated by causing maximal contraction of these muscles by electrical stimulation under general anaesthesia. Of 18 cases so treated 33% were completely relieved and 22% much improved.

During contraction of the pelvic floor muscles the urethra lengthens by 1 cm. or more, to return to its previous length when the contraction ceases.

It is suggested that in the successful cases the maximal perineal muscle electrical stimulation has restored the postural tone of the pelvic floor, so that all increases of intra-abdominal pressure are again accompanied by the normal pelvic floor contraction and lengthening of the urethra. Possibly one maximum contraction of a muscle restores power better than repeated submaximal contractions, the more usual method.

This treatment should always be tried before operative measures are advised, particularly when investigation has shown that in the erect posture the urethra is only 1 cm. or less short of the critical length (3 cm.).

We wish to thank the staff of the Department of Physical Medicine, Manchester Royal Infirmary, for administering the electrical stimulation to these patients.

Hepatocellular Damage with Ethacrynic Acid

K. K. DATEY,* M.D., F.R.C.P.ED., M.R.C.P., F.A.C.C., F.C.C.P.; S. N. DESHMUKH,† M.D.;
C. P. DALVI,‡ M.D., B.SC., F.I.C.A., F.C.C.P.; N. M. PURANDARE,§ M.D.

Brit. med. J., 1967, 3, 152–153

Ethacrynic acid is a potent diuretic agent and has been particularly useful in cases of fluid retention refractory to other diuretic agents (Datey *et al.*, 1967). This is a new drug, and all its toxic effects are still not known. Some side-effects and toxic effects have been well documented. Toxic effects such as cholestatic jaundice, agranulocytosis, and thrombocytopenia have been reported in one patient each (Merck Sharp and Dohme, 1964). A toxic effect not reported so far is presented in this communication.

Case Report

A man aged 25 with rheumatic heart disease (mitral stenosis and aortic stenosis with incompetence), subacute bacterial endocarditis, and gross congestive cardiac failure was admitted to the K.E.M. Hospital, Bombay, on 24 August 1966. He was given the appropriate antibiotic therapy, a low-salt diet, digitalis, and ethacrynic acid. In the first eight days the diuretic response was good and he lost 8 lb. (3.6 kg.) (with 50 mg. of ethacrynic acid daily). However, his urinary output subsequently decreased and an additional dose of 50 mg. of ethacrynic acid was given on alternate days. Various tests, including serum electrolytes, liver function, blood urea nitrogen, etc., were carried out periodically to detect the toxic effects of this drug. Two weeks after starting the therapy mild jaundice was noticed (Fig. 1), and, as we were not certain of its aetiology, the drug was continued and the tests were repeated every four days. When two consecutive tests showed deterioration (Fig. 1), ethacrynic acid was omitted and all other treatment was continued. Though the drug was omitted, the jaundice increased for about a week and then began to recede. It cleared in another two weeks. During this period, when ethacrynic acid was omitted, other diuretics were used. However, they were relatively ineffective. As the condition of the patient deteriorated, ethacrynic acid had to be restarted in a dose of 50 mg. daily. Subsequently the dose had to be increased to 200 mg. daily to get the desired diuretic response. During the next seven weeks hypokalaemia and hypochloraemia often appeared but were corrected by appropriate measures. Seven weeks after restarting this drug mild jaundice developed and the serum transaminase levels were high (Fig. 1). Hence the drug was again discontinued. The jaundice regressed, and six days later, though the serum bilirubin was 1.5 mg./100 ml., the serum transaminase levels had become normal.

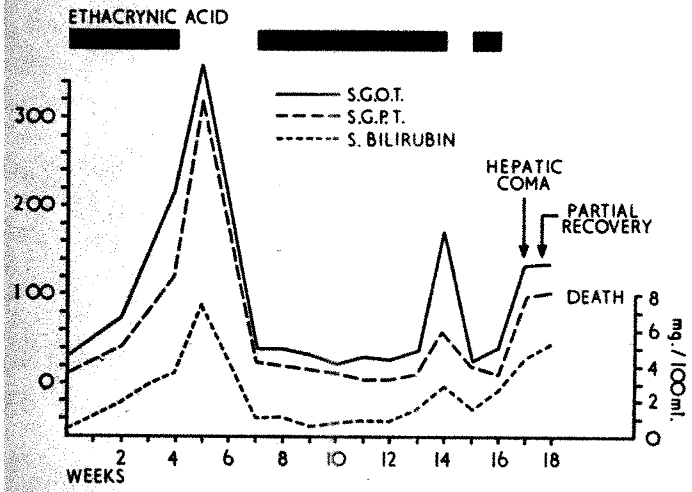

FIG. 1.—Changes in S.G.O.T., S.G.P.T., and serum bilirubin during the course of therapy with ethacrynic acid.

As the cardiac status of the patient deteriorated and there was fluid retention (the weight gain was 2 kg.) during this period, and as other diuretics proved ineffective, ethacrynic acid was restarted, 50 mg. initially. In the next seven days he was given 50 to 150 mg. of ethacrynic acid daily. Jaundice again developed and this time mental changes were also present. The drug was immediately discontinued. Both jaundice and mental changes progressed gradually. In the beginning there was hypersomnia, reduction of spontaneous movements, a fixed stare, and apathy. Intermittent changes included childishness, irritability, and loss of concern for his disease. Speech became slow and slurred, the voice monotonous and often faint. The characteristic "flapping tremors" were observed for a short time, a few hours before coma supervened. He was treated appropriately for hepatic coma, and after three days he came out of coma but still had mental confusion and hypersomnia. No further improvement occurred for the next four days, the serum bilirubin remaining at 4.25 mg./100 ml. and serum aspartate aminotransferase (S.G.O.T.) and serum alanine aminotransferase (S.G.P.T.) 108 and 94 units respectively (Fig. 1). The patient died the next day in congestive cardiac failure.

Post Mortem Examination

The body was emaciated and poorly built. There was an icteric tinge on the skin and in the conjunctiva. The heart was enlarged and showed changes of rheumatic mitral and aortic valve stenosis, with evidence of healed bacterial endocarditis. There was a small healed infarct in the cortex of the left kidney in addition to chronic venous congestion. The lungs and the spleen showed chronic venous congestion. The cut surface of the liver had the typical

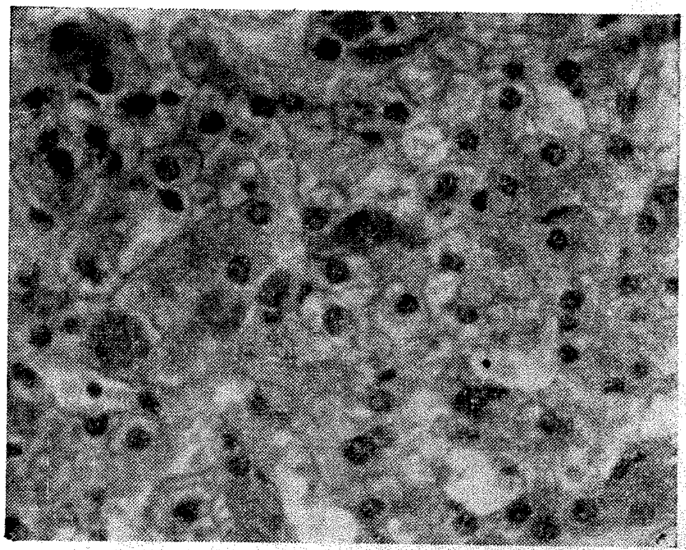

FIG. 2.—Photomicrograph showing area of focal necrosis. (×400.)

---

* Honorary Professor of Medicine, G.S. Medical College, Bombay; Director, Department of Cardiology, K.E.M. Hospital, Bombay; Honorary Physician and Cardiologist, Bombay Hospital, Bombay; Consultant in Cardiology, St. George's Hospital, Bombay.

† Assistant Cardiologist, V.R.A. Research Project, K.E.M. Hospital, Bombay.

‡ Honorary Assistant Physician, K.E.M. Hospital, Bombay; Assistant Professor of Medicine, G.S. Medical College, Bombay.

§ Professor of Pathology, G.S. Medical College, Bombay.

nutmeg appearance of chronic passive congestion. There was a small patch of necrosis, yellowish in colour, in the right lobe. This was rather friable. The gall bladder and biliary tract were normal.

Histology.—The liver showed changes of chronic venous congestion in most of the liver lobules and consisted of dilated central veins and dilated and congested sinusoids. A few cells around the dilated central veins showed changes of necrosis. The periportal connective tissue was slightly increased. In addition to this, in many areas the parenchymatous cells showed evidence of focal necrosis irregular in distribution (Fig. 2), and quite different from that seen in chronic venous congestion. These areas of necrosis morphologically resembled those produced by carbon tetrachloride injury in experimental animals. The necrosed cells showed pyknotic nuclei and indistinct cell walls. The cytoplasm showed hydropic degeneration and in places the presence of amorphous eosinophilic material. A few vacuoles could be seen in some cells. Kupffer cells were prominent and contained increased pigment. The bile ducts showed a moderate degree of proliferation. However, no stagnation of bile could be seen.

Discussion

Jaundice due to drugs is usually hepatocellular or cholestatic and rarely haemolytic. The clinical and biochemical differentiation of the various types is well known.

Ethacrynic acid has been reported to produce cholestatic jaundice in one patient (Merck Sharp and Dohme, 1964); however, to the best of our knowledge there are no reports of hepatocellular damage due to it. Experimentally, it has been proved that this drug is stored in the liver and secreted in the bile (Beyer *et al.*, 1965). The highest concentration of ^{14}C ethacrynic acid, after one week of its intravenous administration, was found in the liver, though this was only 2% of the dose, less than 3% being present in all the other organs (Merck Sharp and Dohme, 1964). We feel that in our patient this may account for the increase in jaundice for some days, even after the drug was withdrawn.

In our case the rise in S.G.O.T., S.G.P.T., and serum bilirubin and positive flocculation tests clearly indicates that the jaundice was hepatocellular in nature. The hepatocellular damage was probably due to ethacrynic acid, because on the first two occasions the jaundice developed when the drug was administered and regressed when it was discontinued. On the third occasion, however, after restarting the drug the patient developed hepatic coma and increasing jaundice. He recovered from the coma with appropriate measures, though the jaundice persisted. The irregular distribution of focal necrosis in the liver, quite different from that seen in chronic venous congestion, which shows centrilobular focal necrosis and resembling morphologically that produced by carbon tetrachloride in experimental animals, is in favour of its being due to the drug and not to acute or chronic heart failure. This correlates well with the clinical observations. As the drug is stored in the liver it is not surprising that hepatocellular damage was produced. Hence caution is required in the administration of this potent drug.

Summary

Ethacrynic acid is a new diuretic agent. Some of its side-effects and toxic effects are well documented, while others have been reported but rarely. A new toxic effect, hepatocellular damage, is reported in this communication.

The drug was supplied by the courtesy of Merck Sharp and Dohme Ltd.

Preliminary Communications

Sugar Consumption in Acne Vulgaris and Seborrhoeic Dermatitis

Brit. med. J., 1967, **3**, 153–155

There is little concrete evidence that diet plays a part in the aetiology of disorders of the skin, except in nutritional deficiency diseases such as pellagra and kwashiorkor. Nevertheless, many authorities implicate diet—dietary excess rather than dietary deficiency—as an aetiological agent, notably in acne vulgaris and, to a less extent, in seborrhoeic dermatitis. Consequently, changes in diet are frequently recommended as part of the treatment of these diseases. Of 10 recent textbooks, diet is mentioned in 9 in connexion with the cause or treatment of acne, and in 6 in connexion with seborrhoeic dermatitis. In neither disease are the authors unanimous; most frequently mentioned, however, is an excessive intake of fat or of carbohydrate, or of both. In addition chocolate is several times specifically mentioned in connexion with acne.

There are three criteria by which one tests the hypothesis that a dietary component is implicated in the causation of a disease (Yudkin, 1953). Firstly, there should be evidence that the diet of persons with the disease differs significantly from that of persons without the disease. Secondly, the symptoms and signs should be those that are known to be, or at least are plausibly suspected of being, caused by dietary imbalance. Thirdly, correction of the dietary imbalance should result in correction of the signs and symptoms.

In this paper we bring evidence of the first sort: that patients with seborrhoeic dermatitis consume significantly more sugar (sucrose) than persons without the disease. We believe that this is the first demonstration of a dietary difference in such patients. We have also shown that there is no such difference in patients with acne.

If the excessive amounts of a dietary constituent are thought to be a possible cause of disease, there are several reasons—evolutionary, historical, and metabolic—why sugar should be regarded as a likely candidate (Yudkin, 1963). It happens, too, than in practice it is more feasible to assess sugar intake than the intake of any other dietary constituent (Yudkin and Roddy, 1966). For these reasons, we measured the sugar intake of patients and control subjects with a short questionary that could be completed in 10–15 minutes by each of the subjects (see Appendix by J. Yudkin below).

The patients were referred to one of us at the skin clinics held at two hospitals. Seborrhoeic dermatitis was diagnosed when the patient presented with severe scaling of the scalp, together either with itchy scaly patches of the sternal or interscapular region or about the eyelids or nasolabial folds, or with intertrigo of the axillae, groins, or retroauricular areas, or with both types of lesions. All the patients had had previous attacks, and the current attack had lasted at least one month. All except one of the 16 patients were males; the ages ranged from 14 to 68.

Acne was diagnosed on the basis of comedones on the face, back, or chest, together with papules, pustules, or cystic lesions. There were nine male and seven female patients, aged between 15 and 27.

The patients with acne and dermatitis were all those who were seen during the period of study, except that, as usual, we did not include in our final assessment those whose sugar consumption, by admission or by implication, had changed.

As control subjects we used two different groups of people. The first were patients suffering from warts and attending the same skin clinics. Again, they were selected only on the basis of their diagnosis and on the apparent constancy of their sugar consumption. They were listed in the order in which we saw them, and from the list we then selected those who matched, as well as possible, the age and sex of the patients with acne or the patients with dermatitis. This was important, because we have found a difference in sugar intake between men and women and at different ages (Salter and Yudkin, to be published). It was, however, possible to find only 13 control patients of appropriate age for the 16 patients with seborrhoeic dermatitis. Moreover, it was not possible to match the distribution of male and female control patients with the distribution of the nine male and seven female patients with acne. For these reasons we used a second group of controls for each disease. These were apparently healthy men and women, either from a London factory or from a large London office. Their sugar intake had been measured during a large-scale survey that was being carried out for other purposes. This second group of controls was also selected from the list of subjects, made in the order in which they were seen, by choosing the first subject in the list that matched in age and sex the first patient with acne or dermatitis, then the first subject that matched the second patient, and continuing until all the patients were matched with apparently healthy control subjects.

RESULTS

The intake of sugar by the patients with acne was not significantly different from that of either group of control patients (Table I). On the other hand, the intake of sugar by the patients with seborrhoeic dermatitis was significantly higher than that of either group of control patients (Table II). This was true both for total sugar and for the sugar taken in tea and coffee ("beverage sugar"). Statistical analysis was carried out with the Mann–Whitney test for Control group 1, and with the Wilcoxon Matched-Pairs Signed-Ranks Test for Control group 2 (Siegel, 1956).

TABLE I.—*Sugar Intake of Subjects With Acne and of Control Subjects (Control 1: Patients With Warts; Control 2: Healthy Factory and Office Workers)*

Group	No.	Age (Mean, Years)	Sugar Intake (g./day)			
			Total		Beverage	
			Mean	Median	Mean	Median
Acne . .	16	19·5	121	103	65	70
Control 1	16	20·0	111	97	47	48
„ 2	16	19·7	120	118	63	55

No significant differences in sugar intake between groups (P > 0·05).

TABLE II.—*Sugar Intake of Subjects With Seborrhoeic Dermatitis and of Control Subjects (Control 1: Patients With Warts; Control 2: Healthy Factory and Office Workers)*

Group	No.	Age (Mean, Years)	Sugar Intake (g./day)			
			Total		Beverage	
			Mean	Median	Mean	Median
Dermatitis	16	38·2	170	185	104	109
Control 1	13	36·5	108	109	65	56
„ 2	16	38·1	110	110	61	57

Significant differences.—Total sugar intake: dermatitis and control 1—P < 0·01. Dermatitis and control 2—P < 0·02. Beverage sugar.—Dermatitis and control 1—P < 0·02. Dermatitis and control 2—P < 0·05.

DISCUSSION

The numbers of patients with either skin disease was small, chiefly because we made every effort to choose those in whom the diagnosis was not in doubt. Apart from this, there was no selection either of the patients with skin disease or of those acting as controls. The selection of the second group of control subjects from the factory and the office was only on the basis of age and sex. The lists of the patients and of the healthy control subjects had been drawn up in the order in which they were seen. This latter list was scanned from the beginning until a subject was found that matched in age and sex the first patient. This procedure was repeated with the next patient, and continued until all the patients had been matched.

In spite of the small number of subjects, we found a significantly higher intake of sugar in patients with seborrhoeic dermatitis than in control subjects. We believe, therefore, that this represents a real difference. We cannot of course say whether or not this relation between disease and sugar intake is a causal one. The findings, however, do suggest that it would be worth while to determine in a controlled experiment the effect of a reduction of dietary sugar on the course of the disease.

Our findings indicate that patients with acne have an intake of sugar no different from that of control subjects. This does not of course mean that diet is not involved in the causation of the disease or that changes in diet would not affect its progress. But further and more elaborate investigation would be required to test this possibility.

SUMMARY

The consumption of sugar (sucrose) by patients with seborrhoeic dermatitis was found to be significantly higher than that of two groups of control subjects. On the other hand, the consumption of sugar by patients with acne vulgaris was found to be no different from that of control subjects.

Mrs. Jill Morland was in receipt of a personal grant from the Medical Research Council while this work was being carried out.

Appendix: Measurement of Sugar Consumption by Questionary

We have reported several studies in which we have measured the consumption of sugar (sucrose) by a method based on a simple questionary. The original method involved the completion of the form by an interviewer (Yudkin and Roddy, 1964). More recently, the questionary has been simplified further so that it can be completed by the subject himself (Yudkin and Morland, 1967). We have given reasons for our belief that the method is reliable (Yudkin, 1964) and we have more recently tested its reliability against the method that involves the subject recording in a diary all the food and drink consumed over a period of seven days (Yudkin and Roddy, 1966).

The simplified questionary is set out below. In all of our studies we have attempted to consider only those persons who, so far as we can ascertain, have had a constant sugar consumption for many years. For this reason we include questions relating to "special" diets, and we eliminate from our final assessments those subjects who we have reason to believe have changed their sugar consumption.

The calculation of the amount of sugar in prepared foods and drinks is made from analyses published in food tables or from figures supplied by manufacturers. As for sugar itself, we take a heaped teaspoon as containing 6 g., a level teaspoon 4 g., a heaped dessertspoon 15 g., and a level dessertspoon 10 g.

I am grateful to Janet Roddy and Jill Morland, who helped to devise and test this questionary, and to the Medical Research Council, who supported the work.

DIETARY QUESTIONARY

NAME .... AGE ....

N.B.—IF THERE IS AN ALTERNATIVE MARKED* PLEASE CROSS OUT THE ONE WHICH DOES NOT APPLY

If your weight has increased in the last few years, are you making a serious effort to check or decrease it ? Yes/No*

If "Yes," are you restricting sweet or sugary foods, or sugar ? ....
....
....
....

If you are on a special diet *now* why are you on this diet ? ....
....

How long have you been on this diet ? ....

Have you *ever* been on any other special diet ? Yes/No*

If "Yes"
Why were you on this diet ? ....
Approximately when did you start this diet ? ....
How long did it last ? ....

If your eating habits have permanently changed as a result of being on the diet, in what way ? ....
....

Go through an average day in your mind, and write down how many cups of tea and coffee you consume:

	Tea	Coffee	Other hot beverages (Cocoa, chocolate, etc.)
Before breakfast	.... cups	.... cups	.... cups
At breakfast	.... cups	.... cups	.... cups
Mid-morning break	.... cups	.... cups	.... cups
Midday meal	.... cups	.... cups	.... cups
Teatime	.... cups	.... cups	.... cups
Evening meal	.... cups	.... cups	.... cups
Bedtime	.... cups	.... cups	.... cups
Other	.... cups	.... cups	.... cups

How much sugar do you take in tea ? ....teaspoons
Are the spoons level or heaped ? ....
How much sugar do you take in coffee ? ....teaspoons
Are the spoons level or heaped ? ....
Have you always taken the same amount of sugar in these beverages ? Yes/No*
If "No," how much did you take before ? ....
When did you change ? ....
Do you *regularly* use artificial sweeteners, e.g. saccharine, saxine, etc. Yes/No*
How long have you used them ? ....
How much of the following do you eat or drink *per week* ?
Sweets, toffees, and fancy chocolates ....lbs. ....oz.
No. of 2-oz. chocolate bars ....
Fizzy drinks, non-alcoholic ....glasses
(inc. tonic water, ginger-beer, etc.) ....small bottles
Fruit squash ....glasses
Fruit juice (tinned or bottled) ....glasses
How many a *week* do you have of the following:
Porridge ....portions
Plain breakfast cereals ....portions
Sugar-coated breakfast cereals ....portions
Jam or marmalade ....teaspoons
Sweet biscuits ....number
Pudding or sweet at midday (including tinned fruit) ....portions
Pudding or sweet for tea or evening meal (including tinned fruit) ....portions
Individual cakes and/or slices of cake ....number
How many spoons of sugar do you take on breakfast cereals ? ....
Are they teaspoons or dessertspoons ? ....
Are they level or heaped ? ....
How many spoons of sugar do you take on porridge ? ....
Are they teaspoons or dessertspoons ? ....
Are they level or heaped ? ....

Medical Memoranda

Hepatitis with Biliverdinaemia in Association with Indomethacin Therapy

Biliverdin is the first bile pigment formed in the catabolism of the haem portion of haemoglobin. In man biliverdin is almost entirely reduced to bilirubin, which is excreted in the bile. The development of biliverdinaemia and biliverdinuria in association with disease, or as an iatrogenic effect, has not been reported. We here present a case of biliverdinaemia and biliverdinuria which developed after the administration of indomethacin (1-*p*-chlorobenzoyl-5-methoxy-2-methylindol-3-acetic acid).

CASE REPORT

A man aged 46 was employed as an unskilled labourer not at risk of exposure to toxic materials or gases. He was admitted to hospital on 14 May 1966 with a four-year history of intermittent joint pains which had been treated with salicylates and phenylbutazone outside hospital. For three weeks before admission he was having indomethacin 75 mg. daily.

On 7 May he had noticed that his urine was green, and soon was off his food and complaining of occasional abdominal pains. The only relevant feature in his past history was that he had suffered from brucellosis in 1957.

On physical examination the skin of the whole body presented a greenish hue, most evident on the trunk, while the conjunctivae were of normal colour. The temperature was 100° F. (37.8° C.); pulse 76/min. and regular; respiratory rate 20/min.; weight 62.6 kg.; and height 160 cm. The liver was palpable 7.5 cm. below the right costal margin. It was firm but not tender. The spleen was not palpable, and there were no intra-abdominal masses. Both hands showed early changes of rheumatoid arthritis. No physical abnormalities were detected elsewhere.

LABORATORY FINDINGS

Hb 13.9 g./100 ml.; P.C.V. 47%; R.B.C. 4,800,000/cu. mm.; reticulocytes 1.8%; leucocytes 7,200/cu. mm., with a normal differential count; blood film—slight anisocytosis, some spherocytic forms, and very occasional poikilocytes, no basophilic, polychromatic, or nucleated erythrocytes; osmotic fragility of erythrocytes—initial lysis at 0.48% NaCl (control at 0.46% NaCl), complete lysis at 0.28% NaCl (control at 0.30% NaCl); E.S.R. 15 mm. in first hour (Westergren); one-stage prothrombin time 17 sec. (control 15 sec.); bone-marrow smear—normoblastic erythropoiesis, normal myeloid series.

The serum was of a definite green colour. The van den Bergh reaction was delayed direct and the total serum bilirubin 3.3 mg./100 ml. Serum aspartate aminotransferase, 55 i.u./l.; alanine aminotransferase 94 i.u./l.; alkaline phosphatase 55 K.–A. units/

100 ml. Blood urea 30 mg./100 ml. and total plasma cholesterol 630 mg./100 ml. Total serum protein concentration 6.0 g./100 ml., with albumin 3.0 g./100 ml. Filter paper electrophoresis showed a slight reduction in serum albumin, with some increase in alpha$_1$- and alpha$_2$-globulins, a significant reduction in betaglobulin, and some increase in gammaglobulins. Serum uric acid 6.2 mg./100 ml. and serum pseudocholinesterase 160 units/100 ml. (range of normal sera 130–310 units/100 ml.). The latex fixation tests for C-reactive protein and the R.A. factor were positive.

The urine was a dark green. It had a *p*H of 5.8 and contained a trace of protein but no glucose or reducing substances. No urobilinogen or urobilin was detected. Fouchet's test gave a strong green spot indicative of biliverdin. The diazo reaction was negative even on the addition of ethyl alcohol. The sediment contained only an occasional crystal of calcium oxalate. *Pseudomonas pyocyanea* was not cultivated from the urine. The faeces were green in colour and also gave a strong green spot with Fouchet's reagent.

The pigment in the urine was isolated in large quantities and identified as biliverdin by the absorption spectrum of its solution in 5% methanolic hydrochloric acid and that of its zinc complex after oxidation with iodine. The spectra observed agreed with those reported by Gray *et al.* (1961a ; 1961b) for biliverdin.

Histological sections (Fig. 1) of liver tissue obtained by percutaneous puncture on 23 May showed centrilobular degeneration, swelling and some fatty change of parenchymal cells, and regeneration of hepatic cells. Both the parenchyma and portal zones contained many neutrophils and mononuclear cells, including plasma cells. Bile stasis, mostly within Kupffer cells, adjacent to the foci of necrosis was evident. van Gieson staining showed increased collagen deposition around the central veins but no increase in the portal tracts. There was some bile-duct proliferation, but the ducts were not obstructed. The overall picture was that of an acute hepatitis.

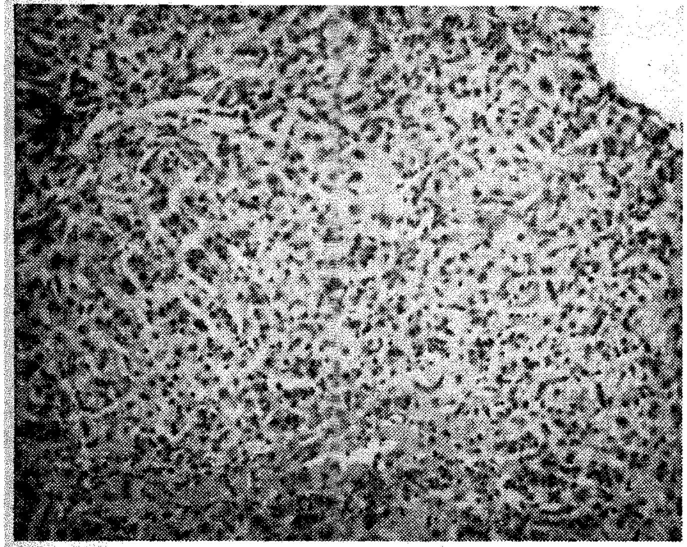

FIG. 1.—Section of liver tissue. Centrilobular degeneration, swelling and some fatty change of parenchymal cells, and regeneration of hepatic cells. There is infiltration of both the parenchyma and portal zone by many neutrophils and mononuclear cells, including plasma cells. (Haematoxylin and eosin. ×165.)

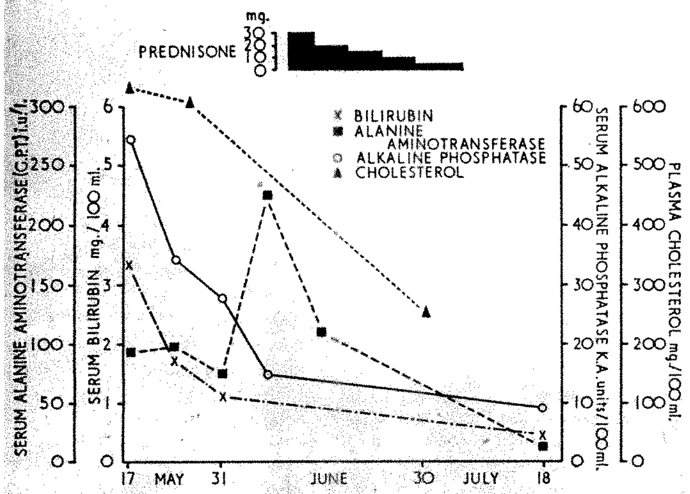

FIG. 2.—Main biochemical changes during the period of observation.

Indomethacin therapy was stopped, and conservative treatment was instituted, with bed rest, a high protein and carbohydrate diet with elimination of fats, and parenteral vitamin supplements for the first three weeks.

The main biochemical changes during the period of observation are shown in Fig. 2. As the serum alanine aminotransferase rose considerably above the level on admission, prednisone was prescribed at an initial dose of 30 mg. daily. This was followed by sustained progress. Within six weeks of the start of prednisone therapy the liver was no longer palpable, the urine and faeces had regained their normal colour, and the serum chemistry became normal.

The patient was discharged from hospital on 5 August 1966 and has remained well.

COMMENT

Temporary mental or neurological symptoms, haemorrhages, haemocytopenias, and even fulminating infections have been reported in the course of indomethacin therapy (W.H.O., 1966). Bruckner and Randle (1965) reported hepatotoxicity associated with indomethacin, but the evidence they produced is very tenuous. In a personal communication the manufacturers claim that there has been no proved case of hepatotoxicity produced by indomethacin. However, Kelsey and Scharyj (1967) have reported a case of fatal hepatitis which was probably due to indomethacin.

The tests of liver function employed and the histological changes in the liver seen in the case presented here are consistent with the diagnosis of cholestatic hepatitis similar to that produced by drugs such as chlorpromazine. In the present case salicylates and phenylbutazone had been taken several months before the illness, while indomethacin had been taken for three weeks before admission to hospital.

Biliverdinaemia presumably results from blockage of the reduction of biliverdin to bilirubin. Singleton and Laster (1965) have demonstrated the existence of high biliverdin reductase activity in guinea-pig liver and spleen. They also demonstrated biliverdin reductase activity in human liver. The development of biliverdinaemia and biliverdinuria has not yet been recorded. Two explanations for its occurrence may be suggested. It is possible that in producing hepatitis indomethacin severely inhibited the activity of biliverdin reductase in the patient's liver, and probably also in the spleen. It is also possible that the patient has a congenital partial deficiency of biliverdin reductase, which came to light as a result of the hepatitis.

We wish to express our thanks to Professor G. P. Xuereb, the Royal University of Malta Medical School, and to Dr. P. J. Scheuer, the Royal Free Hospital, London, for their helpful opinions on the histological sections, and to Dr. Barbara H. Billing, the Royal Free Hospital, London, for advice.

Mycobacterium Battey Infection Resembling Tuberculosis

Brit. med. J., 1967, **3**, 157–158

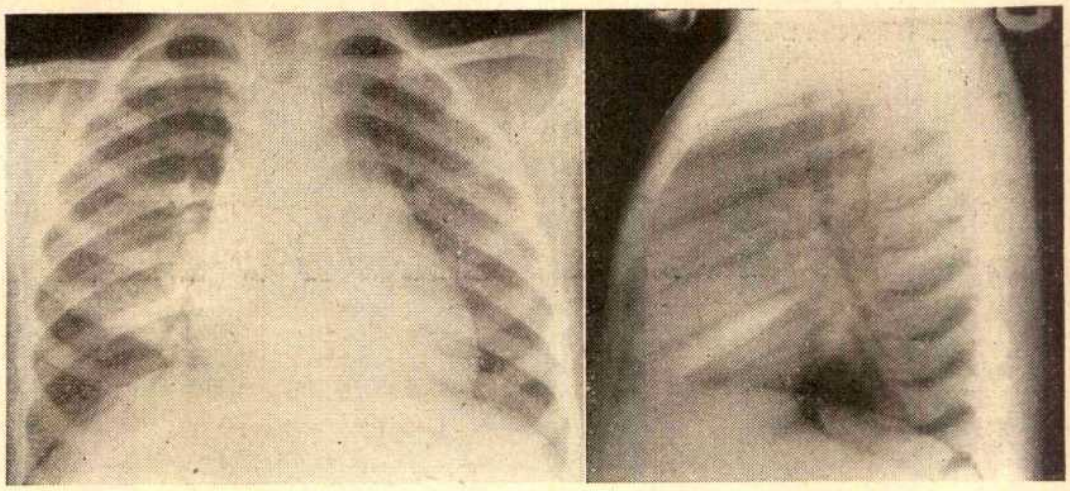
Anonymous (atypical or unclassified) mycobacteria are well established as pathogens for man (Chapman, 1960). They are able to mimic the clinical and pathological manifestations formerly attributed only to *Mycobacterium tuberculosis*. Recent Australian and American experience suggests that there is significant morbidity resulting from infection by anonymous myobacteria. Further, the amount of anonymous mycobacterial infection prevalent sometimes exceeds that of *Myco. tuberculosis* (Smyth *et al.*, 1964 ; Walker and Patron, 1964 ; Carruthers and Edwards, 1965 ; Curry, 1965). The British literature does not reflect a similar experience (Lefford *et al.*, 1966).

One of the anonymous mycobacteria, the Battey bacillus, is recognized as an important and common aetiological agent of pulmonary disease in adults and cervical lymph node disease in children (Smyth *et al.*, 1964). No documented cases of pulmonary disease in children caused by *Mycobacterium Battey* could be found. Neither were any reports found of a child with both pulmonary and lymph node disease occurring together except rare cases of disseminated fatal infection (Volini *et al.*, 1965).

This report describes the case of a child with a pulmonary lesion and cervical adenitis. The hospital admission diagnosis was tuberculosis, but comparative skin testing predicted *Myco. Battey* infection, and this organism was recovered from the lymph node.

CASE REPORT

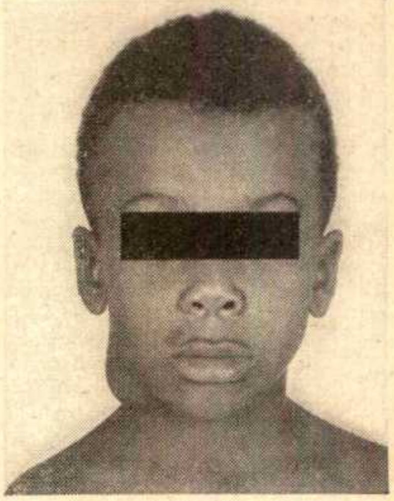
A boy aged 3 years 9 months presented with a six-weeks history of a lump in the right side of his neck which had been increasing in size. At the onset of his illness there were a few days when he felt feverish, but his temperature was not recorded. Before admission he had been treated with antibiotics. No other symptomatology was elicited except for some occasional tenderness of the lump in his neck. One week before admission he had been seen at another hospital where a Heaf test was found to be strongly positive.



FIGS. 2 and 3.—*X*-ray films showing opacity in right middle lobe.

The child had been admitted to our hospital two years previously for investigation of idiopathic convulsions. At that time a Heaf test was recorded as negative. In the year before admission he had had no further convulsions and had been on no anticonvulsant therapy. There was no family history of tuberculosis or any known tuberculous contacts. The family was of West Indian extraction, but had been in Britain for nine years and the patient was born at a local hospital. He had not been given B.C.G. vaccine.

Physical examination showed him to be an apparently fit and alert negro boy at the 50th percentile by height and the 30th percentile by weight for age. A mass protruding from the right side of his neck seemed to involve the submandibular as well as the upper anterior cervical lymph nodes (Fig. 1). The mass was hard, with slight tenderness, and was not fluctuant or warm. It measured 1 by 1½ in. (2.5 by 3.8 cm.) and we could not be sure whether it was a single node or a bunch of smaller nodes matted together. The presence of a 4+ Heaf test on his arm was confirmed. The rest of the physical examination was within normal limits. Temperature on admission was 98.6° F. (37° C.).



[redacted]

FIG. 1.—Photograph of patient, showing mass in neck.

Chest *x*-ray examination showed an opacity in the medial segment of the right middle lobe (Figs. 2 and 3). The sedimentation rate was 37 mm. in the first hour (Westergren) ; haemoglobin 11.9 g./100 ml. ; white blood cell count 10,600/cu. mm., with a differential count of 44% neutrophils, 8% eosinophils, 42% lymphocytes, and 6% monocytes. Sickling test and Paul–Bunnell screening test were negative. Urine analysis was normal. Serum Na, K, Cl, urea, Ca, and P were normal. Cultures of nose, throat, and rectum showed normal flora.

At admission a presumptive diagnosis of tuberculosis was made on the basis of a strongly positive Heaf test in a child under 4 years of age, a recent skin-test conversion, a lesion in the chest, an enlarged "cold" cervical node, and a raised sedimentation rate. Comparative skin testing by the Mantoux technique was performed with purified protein derivative (P.P.D.)-tuberculosis (human), P.P.D.-avian, and P.P.D.-Battey. Three gastric washings were done and the child was given penicillin as a therapeutic trial.

After two weeks of penicillin therapy he remained asymptomatic but had occasional episodes of low-grade fever with no change in his chest lesion or sedimentation rate. His node became fluctuant, and incision with drainage, under cover of isoniazid (20 mg./kg./day) and P.A.S. (300 mg./kg./day), was performed. His tonsils and adenoids were removed simultaneously in order to search for a possible focus of infection.

After surgery, treatment was continued with isoniazid and P.A.S. His node decreased markedly in size with no further drainage after the first month. By the end of three months his sedimentation rate had returned to normal and his chest *x*-ray film had cleared. Six months after onset of therapy he remained well with no evidence of persistence or recurrence.

Bacteriology and Pathology

The skin test antigens (P.P.D.) used for all the Mantoux testing were supplied by the Central Veterinary Laboratory, Weybridge. The human antigen was prepared from strains C, D.T., and P.N. obtained from children with *Myco. tuberculosis* infections. The Battey antigen was prepared from an American strain 100616. The avian antigen was prepared from strain D4 isolated from infected domesticated poultry. All three strains were supplied as containing 2 mg. (100,000 units) per ml. Previous to skin testing the material was freshly diluted to deliver 0.00001 mg. (0.5 unit) per dose. Comparative Mantoux skin testing was done on two separate occasions. The first test compared the avian with the human antigen. Both were positive (greater than 5 mm. induration), but the avian reaction was twice as large as the human. The second test compared Battey, avian, and human antigens placed simultaneously. The Battey showed 15 mm., the avian 12 mm., and the human 5 mm. of induration.

Pus from the node was sent to three separate laboratories. Identiication of the organism was arrived at independently by two of hese laboratories. The other could not distinguish it from *Myco. uberculosis.* The pus was negative by Gram and P.A.S. stains but showed acid-fast organisms by Ziehl–Neelsen stain. Bacterial nd fungal cultures were sterile, but acid- and alcohol-fast bacilli were grown on Löwenstein–Jensen slope after six weeks' incubation. These were subsequently identified as non-photochromogens of the Battey type belonging to Runyon group III. Sensitivities were done with the use of standard strains as comparison and resistance ratios were obtained. These showed the organism to be sensitive to cycloerine but resistant to streptomycin, viomycin, P.A.S., isoniazid, thionamide, and thiosemicarbazone. (We can only note that the linical response as reported was at variance with these in vitro ensitivity tests.)

Histology of tonsils and granulation tissue from the node showed miliary "tubercles" with macrophages, lymphocytes, and multiucleate giant cells with early caseation.

Gastric washings were negative for acid-fast organisms and showed o growth on culture.

Discussion

The role of *Myco. Battey* infection among children in Great Britain is not clear. Marks (1964) mentions four cases of ervical adenitis in children caused by *Myco. avium.* This organism, in his classification, is probably closely related to or synonymous with *Myco. Battey* (*Lancet*, 1962). Marsden and Hyde (1962), in their review of cervical adenitis among children caused by anonymous mycobacteria, did not identify the Battey bacillus in any of their cases.

Skin testing has been done only on a limited scale and generally by the Heaf technique, which provides a poor guide to the degree of tuberculin sensitivity (Griffith *et al.*, 1963). Yet the Battey purified protein derivative has been shown to be an excellent case-finding tool and diagnostic adjunct (Palmer *et al.*, 1959). In addition, it has been suggested that it can be utilized as a screening tool for all anonymous mycobacterial infections as it shows extensive cross-reactions to other mycobacteria (Walker and Patron, 1964).

The issue is further clouded by gross variation in standards of tuberculosis bacteriology. Laboratories very often fail to distinguish between tubercle bacilli and anonymous mycobacteria (Marks, 1965). Yet the therapeutic problem created by these organisms is as great as that due to primary resistance of tubercle bacilli because of their generally poor response to chemotherapy (Lefford *et al.*, 1966).

As a result, we find it difficult to accept that *Myco. Battey* infection, especially among children, is virtually absent from Great Britain. To do so might lead to diagnostic, epidemiological, and therapeutic error (Smith *et al.*, 1965).

ADDENDUM.—We refer readers to two articles which appeared after submission of this paper and which present evidence for differential Mantoux-testing in children (Keay and Edmond, 1966; Mackellar *et al.*, 1967).

We thank Mr. I. W. Lesslie, of the Central Veterinary Laboratory, for supplying the mycobacterial P.P.D. antigens and for his aid in identifying the organism.

Current Practice

TODAY'S DRUGS

Fenfluramine

With the help of expert contributors we publish below notes on a selection of drugs in current use.

Fenfluramine is an appetite depressant recently marketed in this country by Selpharm Laboratories Ltd. under the name Ponderax. It is not subject to the Drugs (Prevention of Misuse) Act, 1964.

Chemistry and Pharmacology

Fenfluramine (trifluoromethyl-3 phenyl-1 ethylamino-2-propane hydrochloride) has been shown in animal studies effectively to reduce food intake.[1] Fenfluramine is not metabolized to amphetamine by animals or man but is present in the blood and urine partly unchanged and as nor-fenfluramine.[2] It is excreted slowly, which may account for its prolonged anorectic effect,[3] and there is accumulating evidence of its fixation in fatty tissues.[4] Like amphetamine and other amphetamine derivatives[5] it may have a direct effect in accelerating lipolysis.[4] It is a sympathomimetic amine which, when given to animals in doses sufficient to cause marked appetite suppression, does not cause overt stimulation of the central nervous system, although both mild stimulating and sedative effects have been demonstrated.[1, 6] Although qualitatively the effect of fenfluramine on the cardiovascular system resembles that of amphetamine, in quantitative terms this effect is much less marked,[6–8] and in both animals and man occasional reduction of the blood pressure has been noted.[9, 10]

Toxic and Side-effects

When given in therapeutic doses the drug may have a sedative effect.[9–13] Diarrhoea has also been reported[10, 14] and may prove troublesome.[14] A few patients experience a symptom complex comprising light-headedness, abdominal discomfort, dry mouth, and generalized tiredness and muscle ache. Hypersensitivity reactions, habituation, and addiction have not yet been reported.

Self-poisoning with fenfluramine has been followed by spontaneous recovery.[2] In the case reported in detail overdosage caused an unusual clinical state of drowsiness with dilated unreactive pupils and sluggish reflexes.

Clinical Use

Clinical experience with fenfluramine in Britain is limited and it is still too early to form a definite opinion of its relative therapeutic value. A number of clinical trials have suggested that it is an effective anorectic agent[9–14] and that it may have several advantages over amphetamine and the amphetamine derivatives in the treatment of simple obesity. Thus, because of the clinical absence of stimulation of the central nervous system, it seems likely that habituation and addiction will not occur; this feature may be of particular value in the treatment of adolescent obesity. In some patients fenfluramine has a sedative effect, even when given in small doses,[9–13] and may be useful in treating those patients with co-existing anxiety states or those who have been disturbed by symptoms of anxiety while taking an amphetamine derivative. Its sedative effect also permits it to be taken in the evenings to try to control late evening or nocturnal hunger. The reported absence of cardiovascular effects allows its use in hypertensive patients[9, 10] when other anorectic drugs are contraindicated. The anorectic effect of fenfluramine may outlast that of other drugs,[14] but this possibility requires to be put to the test. Pending further clinical evaluation it is probably advisable to prescribe only short courses of fenfluramine, which can be repeated if necessary. There is no conclusive evidence that it is substantially more effective than other anorectic agents; it is relatively expensive and like all appetite depressants should not be prescribed indiscriminately. As is the case with all anorexigenic drugs some obese patients do not lose weight appreciably when given fenfluramine.

Dosage

Fenfluramine is available as Ponderax. Each tablet contains 20 mg. of the active ingredient. The recommended adult dose is 2 to 4 tablets daily, though exceptionally up to six tablets daily may be prescribed. Side-effects can be minimized by introducing the drug in a stepwise manner. In children under the age of 12 the recommended dose is 1 tablet daily.

The basic N.H.S. cost of 100 tablets is 38s.

PREPARATIONS AND APPLIANCES

Apparatus for Automatic Preparation and Scanning in Cervical Cytology

Mr. M. M. BODDINGTON and Dr. R. A. DIAMOND, of the Clinical Cytology Laboratory, Churchill Hospital, Oxford, write: Population screening for carcinoma of the cervix has been limited by the lack of trained technicians as well as by inadequate laboratory facilities. This problem could largely be solved by automation by means of a mechanized system with a computer capable of analysing cells and arriving at a decision at high speed.

The apparatus described here is an aid to visual scanning of cervical smears by a cytologist, but is also applicable to automatic scanning by a computer technique. To enable a computer to scan cells rapidly an automated strip method with an even cell distribution is essential (A. Ward, personal communication, 1966).

The Vickers Cytology Screening Apparatus is divided into three parts: the first is the *graphing machine,* which places a line of cells on to a clear transparent strip. This is then transferred to the second part, which is a continuous *staining apparatus* that also automatically covers the cells with a clear Scotch tape. The final machine is the *viewing apparatus.*

Collection of Specimen.—The specimen is presented to the graphing machine as a cell suspension. To do this the cervical smear is collected in the usual way and then the spatula is placed into a solution of 1% Carbowax in 40% ethyl alcohol and transferred to the laboratory. By using a narrow container with a conical bottom containing a measured amount of fixative, the container can be placed direct into the centrifuge after removing the spatula. Suspending cells in a Carbowax alcohol solution allows them to be dried on the film strip previous to staining without spoiling the specimen.

GRAPHING MACHINE

The graphing machine has three functions: (1) aspirating excess fluid from concentrated cells; (2) pretreating a transparent film strip (Melinex I.C.I.) with celloidin (Necoloidine B.D.H.); and (3) drawing along the centre of the Melinex a linear film of cells.

A spool of Melinex 250 metres long is mounted on to the machine and laced under the Necoloidine writer through a guide over which the cell writing pen is located. After the cell writer the film is passed through the numbering mechanism, thence through the specimen dryer, and on to the take-up spool (Fig. 1).

The Necoloidine is applied to the Melinex by what might be described as an outsize ball pen. It is hoped that when in production the film will be supplied already coated with Necoloidine. Because the cells are fixed in solution Necoloidine-treated film must be used to prevent the cells from being washed off the film.

The cell writing pen is a linear reciprocating peristaltic pump. It differs from the normal peristaltic pump in that it draws fluid into its pliable plastic tubing and exhausts it out of the input. The unique feature of the pen is that the contaminated tubing is withdrawn, cut, and discarded. The plastic tubing is fed through the top of the pen from a reel, so that on drawing the contaminated tubing out it is automatically replaced by fresh tubing.

After centrifuging the tube is placed under a pipette and the excess fluid aspirated through a pump. The amount of fluid withdrawn is controlled by the attendant and the cell deposit thoroughly resuspended.

The pen is loaded by sucking up the concentrated cells; it is then placed over the centre of the Melinex strip with the protruding plastic tubing, which acts as a nib touching the strip. A motor is started, the tape is drawn beneath the pen, and the peristaltic pump reverses and deposits a line of cells for 61.5 cm., which corresponds to the area scanned on a normal microscope slide when a 5-cm. coverslip is used.

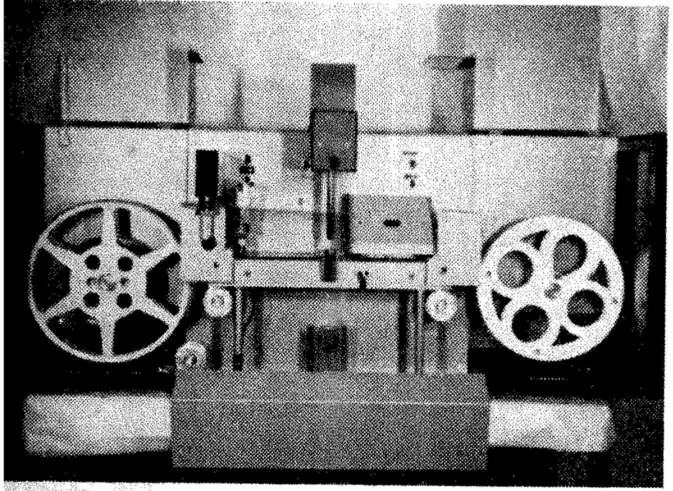

FIG. 1

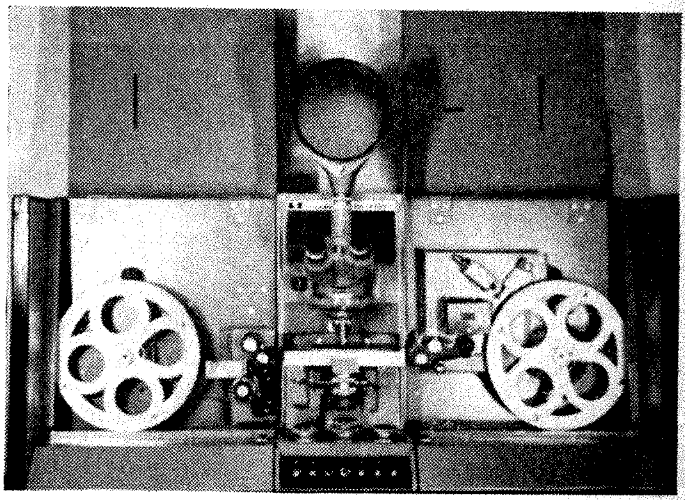

FIG. 3

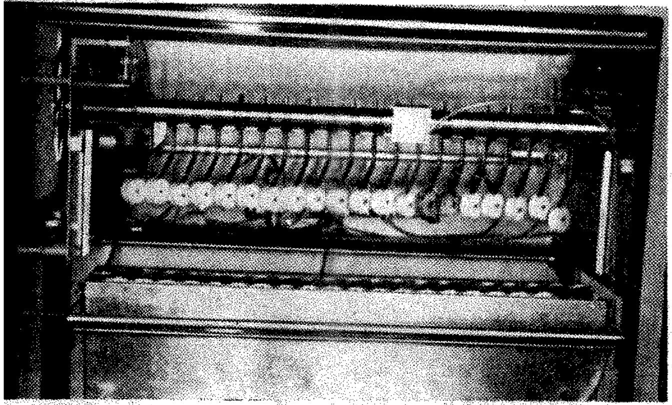

FIG. 2

FIG. 1.—Graphing machine, showing the peristaltic pen (centre) which deposits a line of cells on the transparent film strip as it passes. FIG. 2.—Continuous staining apparatus, showing the series of rollers over which the film strip is looped. Beneath them is the unit containing the individual staining-baths which, when raised, immerses the rollers. FIG. 3.—Viewing apparatus. The prepared film on the left passes under the objective of the microscope (centre) for viewing on the screen or through the binoculars.

Materials.—(*a*) Melinex, 16 mm. wide by 0.075 mm. thick by 250 m. long (I.C.I. product); (*b*) 1% solution of Necoloidine in equal parts of ether/alcohol; (*c*) translucent silicone rubber tubing size 1 by 0.5 mm. Quality P.C. 156.

STAINING APPARATUS

The spool from the graphing machine is loaded on to the continuous staining apparatus and the free end of the prepared film is welded on to a leader strip of Melinex, which is already fed through the apparatus. The prepared film is thus fed backwards through the staining process; the last 9.3 m. must be clean film to act as a leader for the next spool (see Fig. 2).

The staining and clearing process consists of 20 baths, the Papanicolaou technique being used. After the specimen has been cleared in xylene a line of D.P.X. mounting medium is drawn over the line of cells. The film is then covered by Scotch tape, 2 mm. narrower than the film, by passing them together through a roller system so that the tape is pressed evenly over the Melinex. The apparatus is fitted with five safety switches, which stop the machine if any faults develop during the processing.

The prepared specimen is taken up on another spool ready for immediate use on the viewing apparatus, having taken 13.25 minutes for the first specimen to be completed and then 1 minute for each subsequent specimen.

VIEWING APPARATUS

The specimen reading unit is a standard-type microscope, but differing from today's mechanical practice in that the body is focused and the stage remains fixed. The spool of specimens is loaded on the left of the microscope and the strip is located beneath the objective by a simple gate. The strip is drawn past the objective, the operator controlling the scanning speed through a start-stop and variable-speed control (Fig. 3).

The operator can reverse the strip by motor and centre any given field by normal stage control for examination under high power. A precision punch is provided for accurately marking abnormal cells, so that instant review of these can be made when the punched hole passes through a trigger-switched clamp. A similar electromechanical clamp holds each specimen number for reference during the passing of that specimen.

The specimen is viewed through binoculars or on a screen with the normal low- and high-power lens system.

The specimens are conveniently stored on the spools, each 250-m. reel containing up to 200 smears.

DISCUSSION

Initially this apparatus was designed to fit a computerized scanning system, and it is expected that ultimately a pattern recognition computer or similar prescreening device will take over much of the human effort involved in scanning cervical smears (Ward and McMaster, 1966). When this ideal set-up is established the positive material must still be checked by a cytologist, and this continuous-feed mechanism must be readily adaptable for human use.

The first essential is that the cells should be recognizable to the human observer and that the staining technique should therefore be the Papanicolaou method. The technique of suspending the cells in a Carbowax-alcohol solution and allowing them to dry gives a staining reaction almost identical with that by the routine "wet fixation" method used for smears on glass. The suspension gives an even distribution of cells with less clumping, and the gross appearances are somewhat different from those in a direct-smear preparation.

Our experience is similar to that of Davis and Jones (1966) using the cytopipette in that cellular patterns are different and require experience in interpretation. The cytopipette method is readily adaptable to this automated system. Abnormal cells do not appear in natural collections, and, though not so readily picked up by the human eye, the scatter distribution is necessary for a computer "eye."

A method of making and staining strips of cervical smears having been developed, the viewing machine was the next essential. This had to be capable of scanning the film strips without computer aid, and the present model can therefore be used for routine screening identical with the glass-slide method in speed and efficiency.

A detailed time comparison between the routine slide method and the Vickers Cytology Screening Apparatus shows them to be very similar. The staining time is slightly increased; but this is no disadvantage, because it does not involve technician time. Moreover, the "smears" are in numerical order and are ready to scan immediately. The technician time involved in the process is equivalent, apart from 51 seconds required to make each smear on the graphing machine.

The advantages of the system are the uniformity of the preparations, the fixed numerical sequence of forms and smears, and the consequent ease of filing. Staining of large numbers can be carried out overnight, and the automatic selection of previously marked cells for checking is an added refinement.

The main advantage of such a system would be felt in large population surveys. The greater the number of smears to be screened and the larger the laboratory the more efficient will be an automated apparatus of this nature.

Further trials are in progress to substantiate the efficiency of the Vickers Cytology Screening Apparatus in enabling malignant cells to be more readily detected and to shorten the time involved in scanning. Attempts are being made to improve the initial cell suspension and to produce a differential nuclear stain, so that investigations into the effectiveness of a prescreening device attached to this apparatus can be completed.

The application of this system to other pathological services is under investigation.

This work was initiated in the Churchill Hospital Cytology Department by Dr. A. I. Spriggs, who has encouraged and advised us throughout the development of the project. This work was supported by grants to one of us (R. A. D., Research Assistance Area Department of Obstetrics and Gynaecology) from Tenovus and Vickers Instruments, and to Dr. Spriggs by the British Empire Cancer Campaign. The instruments have been designed and constructed by Vickers Ltd., Vickers Instruments, under licence from Mr. P. A. Rock (U.K. Patent No. 1036776 and various overseas patent applications) and under the supervision of Mr. F. H. Smith and Mr. J. F. Taplin (Research Department), and the combination of the complete system was the work of Mr. E. W. Meyer (Forward Development).

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Health in Malawi

Q.—*Are the dangers to health for European children greater in Malawi than at home? Are comparative mortality figures available for children under 5 years of age? What are the main causes of sickness and death in this group?*

A.—Comparative mortality figures for children under the age of 5 years in Malawi are not available. The most recently available data on this subject are those contained in the *Last Report on the Public Health of the Federation of Rhodesia and Nyasaland during the Year 1963 Presented to the Federated Liquidating Agency.*[1] In this report the infantile mortality rate among Europeans in Malawi is given as 3.9 per 1,000, but it is based on only one infantile death. The crude death rate among Europeans in Malawi is reported as 3.3 per 1,000.

In general, those living in this part of Africa would need to take special precautions against malaria and bacillary and amoebic dysentery. The usual precautions against smallpox, yellow fever, and poliomyelitis should also be taken. Though the dangers to health for European children in Malawi are greater than they are in Britain, standard precautions will reduce these dangers to a very low level. Details of such precautions will be found in the publication entitled *Notes on the Preservation of Personal Health in Warm Climates.*[2]

Diet for Alcoholics

Q.—*What diet (and particularly what amount of protein) should be advised for a man who drinks 10 to 20 pints of beer a day?*

A.—The important point is that the heavy drinker should eat a balanced diet containing normal amounts of protein. When alcohol is used as a substitute for food calories and carbohydrate are the main components and liver damage may occur. There is also the observation that if liver damage is already present recovery will follow the giving of an adequate diet, even if drinking continues. A heavy drinker may also need extra vitamins, especially of the B group.

But, despite this, the proper management of such a patient is surely to try to get him to reduce his alcohol intake.

Sterilizing Floors of Swimming-baths

Q.—*What suitable agents are available for sterilizing plimsolls and the floors of swimming-baths to control the spread of warts? Can x-irradiation be used for sterilizing plimsolls?*

A.—There does not appear to be any information on the sensitivity of the wart virus to available methods of disinfection. In structure it is like a polyoma virus, which contains D.N.A., and some D.N.A.-containing viruses have been shown to be readily inactivated by chlorine (e.g., by 10 minutes' contact with the 0.3 to 0.5 parts per million of free residual chlorine commonly present in swimming-bath water).[1] Frequent washing of the floors of swimming-baths and changing-rooms with chlorine solution would be expected to reduce the hazard of wart infection. Almost continuous cleaning and sluicing has been found effective in removing the agents of tinea pedis from the floors of swimming-baths.[2]

If plimsolls are not exchanged there should be little or no risk of acquiring warts from them. X rays and gamma rays inactivate viruses, and could undoubtedly remove the virus of warts from plimsolls, but large doses may be required to inactivate some viruses.[3] Immersion in a hypochlorite solution would probably be effective. Disinfection of footwear, however, is likely to be impracticable.[4]

Withdrawal of Morphine

Q.—*Is bronchopneumonia a recognized complication of the withdrawal of morphine from patients who have been on regular doses of the drug for some time?*

A.—Among the so-called non-purposive symptoms which may follow the withdrawal of a narcotic drug are insomnia; anorexia; sneezing; lacrimation; coryza, with alternate chills accompanied by gooseflesh; and sweating. In addition the patient often does not eat or drink, and so there may be loss of weight, dehydration, and a disturbance of acid/base and electrolyte balance.

Morphine causes respiratory depression, and it is said that this continues into the withdrawal period.[1] Thus, though one would not claim that bronchopneumonia was a recognized complication of withdrawal, a patient in the withdrawal phase is clearly in a condition in which he is very susceptible to the development of bronchopneumonia.

Manual Removal of Placenta

Q.—*Should manual removal of the placenta normally be carried out under anaesthesia?*

A.—Normally general anaesthesia should be used in the operation of manual removal of the placenta. It can be very painful for the woman, and it may cause "shock" when done without anaesthesia. Sometimes it can be very difficult, and it is wise to be prepared for anything that may happen.

With the widespread use of controlled cord traction after the injection of Syntometrine (ergometrine maleate and oxytocin) manual removal is not often needed, and when it is there is no need for undue haste, since bleeding with the placenta still in the uterus is then usually negligible. There is therefore time for proper deliberation in performing the operation.

Despite this, however, it is quite possible manually to remove the placenta after an injection of only an analgesic such as pethidine, and even on occasion with only obstetric gas analgesia if the operator is expert and gentle. Especially is this possible when the placenta has separated and is lying within the lower segment, a fact which can be verified by sterile vaginal examination in the third stage. When the placenta is not definitely separated from the uterine wall general anaesthesia certainly ought to be used.

Oral Contraceptives and Psychosis

Q.—*A woman who had puerperal schizophrenia six years ago has recently had similar symptoms, and these coincided with taking an oral contraceptive for nine months. Is there any evidence that taking oral contraceptives can lead to the puerperal type of schizophrenia in a susceptible individual?*

A.—I know of no published work on this. However, it is not unreasonable to suppose that oral contraception, by inducing a state of pseudopregnancy, has produced in this patient a biochemical milieu similar to that which precipitated her puerperal schizophrenia. In the circumstances I think another method of contraception is indicated.

Tetanus from Water Buffalo

Q.—*Is there evidence that Clostridium tetani is carried by the water buffalo in India, and that their droppings are a source of infection in children who handle dung freely?*

A.—I have been unable to find any positive proof that *Clostridium tetani* has been isolated from the stools of water buffalo in India, but it may be taken that their faeces are a potential source of this organism. All herbivores are likely to swallow spores of *Clostridium tetani* from time to time when they eat grass vegetation contaminated with these organisms. Their droppings should therefore be regarded as a potential source of tetanus.

Notes and Comments

Oral Contraceptives and Epilepsy.—Dr. JEAN MCARTHUR (Family Planning Association, Liverpool 1) writes: I read with interest your expert's reply ("Any Questions?" 17 June, p. 752) to the question on prescribing oral contraceptives for an epileptic woman. The following case suggests that some discrimination should be used when prescribing oral contraceptives in this condition.

A woman aged 23, para 3, who attended a Family Planning Association clinic in January 1965, was being treated with phenobarbitone and Epanutin (phenytoin) for epilepsy, which began in 1962 during her second pregnancy. Lyndiol was prescribed and taken from February to June 1965. During this time the number of convulsions increased, and after six in rapid succession she was admitted to hospital. The Lyndiol was discontinued, because the increasing number of fits was thought to–be due to fluid retention caused by the oral contraceptive.

The patient was anxious to continue on an oral contraceptive, so Gynovlar was prescribed from August to November 1965, and changed to Ovulen after persistent amenorrhoea. From November 1965 until now she has taken Ovulen with satisfactory results. Since discontinuing Lyndiol she has had only occasional convulsions, usually associated with an infection or emotional upset. The anticonvulsant therapy has remained the same throughout.

Lyndiol (usually so free from side-effects in normal patients) together with Lyndiol 2.5, Conovid, and Conovid E belong to the group of oral contraceptives which are predominantly oestrogenic in effect. These should perhaps be avoided in conditions aggravated by fluid retention.

OUR EXPERT replies: The point that needs emphasizing is that the woman about whom the question was asked had not had a fit for 15 years. A woman who has not had any fits for 15 years is not to be regarded as having epilepsy. She should be thought of and treated as a healthy woman.

In considering patients who do have epilepsy, however, we should realize that the biochemical effects of the hormones affecting the menstrual cycle are not yet adequately known. The question of the existence of fluid retention in the body, including the brain, is still being studied, and our knowledge is still inadequate. Any observations on the effects of the different contraceptive pills, including their effects in epileptic patients, should therefore be noted, and when enough interesting data have been collected they should be published.

Book Reviews

Neurological Genetics

The Genetics of Neurological Disorders. By R. T. C. Pratt, M.A.(Oxon.), D.M., F.R.C.P., D.P.M. (Pp. 310+vii. 80s.) London: Oxford University Press. 1967.

This volume, the third in a series on medical genetics, brings together a large amount of scattered information on a wide range of disorders, from the congenital malformations to the presenile and senile dementias, and from the systemic degenerations and leucodystrophies to higher-level disorders, such as dyslexia and stammering. The muscular dystrophies are included, as are migraine and enuresis, but Down's syndrome (mongolism) is not. For genetical principles and for clinical descriptions of the commoner diseases the reader is expected to look elsewhere. Here he will find much concise information on epidemiology, familial risks, twins, parental consanguinity, modes of transmission, metabolic errors, chromosome anomalies, linkage, and biological fitness as measured by fertility.

Neurological diseases are well suited to genetical study because the diagnosis can often be made in secondary cases even when they cannot be examined. Moreover, the nervous system is particularly susceptible to disturbances of metabolism during its development, and later to degeneration of different parts. Even in the infections there may be a genetic factor, as in poliomyelitis and in the parkinsonian phase of encephalitis lethargica. In the idiopathic spinocerebellar ataxias, spinal muscular atrophies and basal ganglia disorders, in the muscular dystrophies, and in some of the epilepsies, evidence for hereditary factors is strong or conclusive, though the mode of transmission varies ; and the same clinical syndrome may include several genetical entities. The risk of epilepsy is highest—about 6%—in close relatives of patients with epilepsy of centrencephalic type beginning early in life. In motor-neurone disease transmission is dominant in some families, but obscure, possibly polygenic, in the majority. In the adult form of myasthenia gravis there is, rather surprisingly, no increase in risk among relatives. In multiple sclerosis there is need for further work by neurologists aware of the requirements of genetical investigations to unravel the environmental and genetical components.

Many inherited disorders affecting the nervous system, like the acquired disorders they may resemble clinically, are due to metabolic faults in the liver or other organs and relatively accessible to study. Much of our knowledge of neuroenzymology is derived from animals, whose brain structure differs from ours, and practically nothing is known of the nature of the enzyme defects in the dementias and systemic degenerations in man. The hopeless prognosis in these disorders and the threat to future generations would seem to justify more histochemical investigation of the human brain, including biopsy.

This book is an admirable work of reference for the medical geneticist, for the paediatrician, neurologist, or psychiatrist, and for the postgraduate student. There are 2,814 references, which in an appendix are conveniently allocated to specific topics and ranked in order of importance. The author's style is lucid and compact, with a pleasing lightness of touch. The standard of production is high. The book epitomizes the new look of modern neurology, now ready to reap the fruits of biochemical discoveries for which clinical and genetical studies have prepared the soil.

D. W. K. KAY.

Story of Charing Cross

The Two Pillars of Charing Cross. The Story of a Famous Hospital. By R. J. Minn. (Pp. 235+xiv ; illustrated. 36s.) London: Cassell. 1967.

This book gives a very readable account of the history of Charing Cross Hospital and Medical School based on the hospital records and on information obtained from recent members of the medical and administrative staff. We found no reference to Dr. William Hunter's *Historical Account of Charing Cross Hospital.*

The book is written in a popular style by a well-known writer and includes brief biographies of many distinguished persons associated with the hospital and school. The pages are enlivened by unusual incidents (as, for example, when Joseph Chamberlain was treated as a "casualty") and by some amusing stories, though we found that related on page 142 scarcely credible.

The hospital was founded by Dr. Benjamin Golding, who in 1818 opened the West London Infirmary and Dispensary in Suffolk Street. In 1821 a move was made to Villiers Street, where 12 beds were provided and students taught. In 1827 the name was changed to Charing Cross Hospital and in 1834 a new hospital of 60 beds was built and opened on the present site. The medical school was lodged in the basement and it was there that David Livingstone and T. H. Huxley were taught medicine. Dr. Golding, who had been for so many years physician to and director of the hospital, died in 1863.

The next 50 years saw great progress. Trained nurses were introduced and a nurse-training school founded, a new medical school was built in Chandos Street, and two extensions of the hospital brought the number of beds to almost 300, but, to our disappointment, we are told relatively little about the moving spirits behind these important developments.

The period before and during the first world war was a difficult time for all voluntary hospitals, but George Verity, who became chairman of the hospital council, worked hard to maintain the efficiency of the hospital, and it was he who in 1921 was the means of bringing in Philip Inman as secretary and superintendent. Inman, possessed of great administrative ability, sound judgement, keen business acumen, and a conciliatory manner, soon made his influence felt, and on the death of Verity in 1936 he was elected chairman of the hospital council. He skilfully guided hospital and school through the troublous times, smoothed the difficulties incidental to the change-over to the National Health Service, and helped to find a suitable site for the future greatly enlarged hospital. His elevation to the peerage and further activities are well known to all.

We hope that in future editions some reference may be made to Dr. Thomas Watts Eden and Sir Thomas Fairbank. On page 176 the account of the accident to Sir Herbert Waterhouse needs modification, for he recovered from the immediate effects of the injury but died suddenly a year later.

ZACHARY COPE.

International Comparisons by Graphical Presentation

Statistical Atlas on Public Health in the Federal Republic of Germany. Vol. 2. 1965 edition. In German, English, and French. (Pp. 228 ; illustrated. DM. 25.) Stuttgart and Mainz: Kohlhammer. 1966.

In addition to the report on Public Health in the Federal Republic of Germany this volume contains international comparisons of medical and vital statistics. A translation of the text is given in English and French.

The book consists of three sections: geography, demography, and medical statistics. The short first section of eight pages gives the distribution of the population density of the world by climate and country. In addition to the tables the data has been displayed in two coloured maps which also give the cities with a population of one million or more inhabitants. In the 36-page section on demography the comparisons are confined to six countries: the Federal Republic of Germany, England and Wales, France, Italy, Sweden, and the United States of America. These countries were selected partly because of the quality and comparability of their statistics.

The data have been displayed in tables and a graph has been drawn for each table. The experience of each country has been shown by a different coloured line. These coloured lines allow a ready and easy comparison to be made of the trends. The section on demography consists of five headings: population, number and changes during the past 60 years; age distribution; births and deaths; life expectancy; infant mortality and stillbirths. The United States had the largest increase in population and the largest proportion of children under 15 years of age, and the smallest proportion of the population aged 65 years and over and the smallest proportion of the population at working ages (59.6%). The Federal Republic of Germany had the largest proportion of persons at working ages—67.1%—and had the second largest increase in population. In the United States the increase was due to an excess of births over deaths, while in the Federal Republic of Germany about half the increase was due to refugees from East Germany. The expectation of life at birth was highest in Sweden, 71.6 years for males and 75.4 years for females, and the lowest expectation of life was in Italy, 65.8 years for males and 70.0 years for females. Sweden had the lowest infant mortality during the past 60 years and Italy the largest during the past 40 years. In recent years Sweden had the lowest stillbirth rate and Italy the largest. The low stillbirth rate in the Federal Republic of Germany is in contrast with the relatively high infant mortality.

The 152-page section on medical and vital statistics starts by considering the incidence of infectious diseases and the incidence of quarantinable diseases throughout the world. Maps are included to illustrate the distribution of leprosy, malaria, plague, relapsing fever, cholera, yellow fever, and smallpox. The remainder of this section gives the crude death rates for each sex and the stardardized death rates for the principal causes of death in the six countries. Some interesting differences occur between the trends of the different countries. For example, in 1961 the standardized mortality rate for cirrhosis of the liver among French males was 13 times that of the males in England and Wales, and in 1962 the rate for senility in the Federal Republic of Germany was 38 times the rate in the United States. The final chapter gives the number of different kinds of hospitals in the six countries, the number of beds, the number of doctors in each specialty, and the number of medical and auxiliary personnel.

Epidemiologists and medical and vital statisticians interested in the geographical distribution of disease and in the comparability of international mortality statistics will find material in this book that will interest and give rise to speculation. Even for these six countries, chosen because their statistics were thought to be sound, it is evident that any conclusions drawn from international comparisons must be subject to qualifications.

W. J. MARTIN.

Cancer: Diagnosis and Treatment

Progress in Clinical Cancer. Vol. 2. Edited by Irving M. Ariel, M.D., F.A.C.S. (Pp. 375+xvi; illustrated. £5 11s.) London: William Heinemann. 1966.

In the total effort to gain the mastery over cancer the clinician has a vital contribution to make. It is exemplified by the contents of this book, which also demonstrates the fact that progress is being achieved in certain major directions. The editor has grouped the material provided by 49 authors into six sections dealing with general considerations: diagnosis, surgery, irradiation, chemotherapy, and specific neoplasms. Selected references are given and a detailed index provided.

Three important subjects for the clinician are dealt with in the opening section. Under the title "The Molecular Biology of Cancer" attention is focused on the cancer cell, highlighting the genetic system, including D.N.A., three types of R.N.A., amino-acids, proteins, and enzymes. Suggestions emerge concerning possible therapeutic approaches, including chemotherapy, when substances might be found with specific inhibitory action on various parts of the genetic apparatus. Such a discussion points the way to rational cancer chemotherapy. Immunity is discussed in a short chapter where the theoretical excitement of its possibilities is sensed without perhaps present practical foundations; in fact the author advances as "perhaps the most cogent reasons for optimism about the future of immunity in cancer is the possibility that a viral etiology of some malignant neoplasms may be established." But in the case of human cancer this has not yet been done. Will Burkitt's lymphoma be the first? The third subject dealt with in the opening section is blood flow to tumours. This has important practical implications for the clinician using regional perfusion and infusion, and the radiotherapist applying external irradiation or employing radioactive isotope therapy.

Contemplation of the end-results of cancer treatment today cannot engender any complacency with cancer diagnosis, for in so many patients when the tumour is seen or felt dissemination has already occurred. The section devoted to diagnosis is therefore welcomed, for here is the experience of the cancer detection centre at the University of Minnesota established in 1948, which merits careful study and emulation. The value of this work is apparent. The author states, "Our data indicate that routine annual examination by methods in current use will permit detection of the majority of the commonly occurring cancers while relatively early in their course, confined to the organ of origin, and productive of relatively few or no symptoms."

In the section devoted to surgical treatment the editor has chosen six subjects. Rectal cancer in the female creates practical problems because of the close proximity of the vagina, uterus, and ovaries, leading to residual cancer in the pelvis after the Miles operation. An anatomical study is described of the rectal lymphatics and the radical operation which was evolved for rectal cancers 2 to 4 in. (5–10 cm.) above the anal verge.

Other subjects include partial hepatectomy, exarticulation of the innominate bone, immediate ambulation following amputation, cordotomy, and adenomammectomy. The reviewer cannot entirely approve the latter chapter concerning a "technical procedure for biopsy, fibrocystic disease, plastic repair, and breast hypertrophy." There are so many aspects of breast cancer which should be discussed, so why introduce other subjects into a cancer book? Is a cancer still "suspicious" with peau d'orange present? And in this stage a drill biopsy is surely better than "a wide elliptical excisional biopsy."

Important aspects of radiotherapy are considered in five chapters: split-dose radiotherapy; preoperative irradiation for bronchogenic carcinoma (where evidence of its value is given in superior sulcus syndrome carcinomas); hyperbaric oxygen as an adjuvant to radiotherapy; treatment of cancerous effusions; and radioactive microspheres in advanced cancer. Only hyperbaric oxygen as an adjuvant to systemic chemotherapy represents the chemotherapy section; the author believes the results have been improved to a small degree. The remainder of the book is devoted to specific neoplasms, showing the progress made in diagnosis and treatment. The editor and his large team of collaborators have made a valuable contribution to cancer literature; this book repays study, and it is pleasing to read the tribute to Owen H. Wangensteen, to whom the book is dedicated.

RONALD W. RAVEN.

Scoliosis

Scoliosis. By Robert Roaf. (Pp. 147+xi; illustrated. 37s. 6d.) Edinburgh: E. & S. Livingstone. 1966.

The first half of this monograph is concerned with an analysis of scoliosis under the headings of anatomy and mechanics, followed by a discussion on the author's concept of the basic causes of the progressive deformity. This part of the book is often challenging and controversial and a considerable stimulus to thought. The current conventional ideas on conservative and operative treatment are reviewed and the serious shortcomings noted. The author's attempts to reverse the forces causing an increasing lateral deformity by epiphysiodesis of the vertebral bodies on the convex side in children are described. When considering treatment Professor Roaf emphasizes the work of Chaklin in Moscow on partial vertebral body resection in reducing lumbar scoliosis and lumbar lordosis, which he considers an important cause of progressive deformity.

This book is no pedestrian reprinting of accepted textbook ideas about the aetiology and treatment of scoliosis, but a statement of personal individualistic views on a subject that has interested Professor Roaf for a number of years. I can thoroughly recommend this monograph to all surgeons and physicians concerned with scoliosis—both to read now and to have at hand for future reference.

C. W. MANNING.

Using a Health Visitor

The Principles of Health Visiting. Edited by P. J. Cunningham, B.A., S.R.N., S.C.M., H.V.Cert. (Pp. 262. 25s.) London: Faber & Faber. 1967.

"In modern health visiting the whole spectrum of family experience is the province of the health visitor," writes Dr. J. G. Howells in one of the two excellent chapters he contributes to this book. "The health visitor and the general practitioner see illness in the community as it is."

The general practitioner certainly does, but the health visitor under the present tripartite system doesn't get the chance. *Family Needs and the Social Services* (P.E.P., 1961),[1] to which two of the health-visitor contributors refer, brought out this point. Only 55% of all the families surveyed—and they included only families with one or more children under 5—had ever used the health visitor, compared with the 99% who had used the general practitioner. A much smaller percentage of the elderly and of families with grown up children and teenagers can have used her, yet they also have social problems which the health visitor might help solve. Dr. Lumsden Walker in another chapter on "The Family" delineates some of them. It is left to Miss Greta Flack, who had the unusual advantage of working with both an enlightened medical officer of health and enlightened general practitioners, to show how, by attaching her to a group practice, the health visitor can come into her own. It took a little time for everyone to realize that the basic essential—a room to work in—could be provided by the simple expedient of using one of the partner's consulting-rooms when he wasn't there. When she really did become part of the practice the advantages stood out. She increased her scope of work in all spheres, but especially in mental health, care of the aged, and social difficulties. "You really know us," said the patients.

The book is uneven. Some of the chapters are textbook descriptions of symptoms and procedures rather than accounts of how to apply principles to modern conditions. Too many administrators contribute standard chapters which might have been appropriate before the last war. For example, under scarlet fever, "if the patient is nursed at home isolation and concurrent disinfection should be rigidly enforced"—but no general practitioner describes co-operation with health visitors. Dr. Harry Levitt, in an admirable survey of the situation, refers to papers from all parts of the country about successful attachments of health visitors (as well as district nurses and midwives) to practices, but none of the authors is included.

This is a commendable first shot at defining the principles of health visiting, but in the second edition the editor should impose her stamp upon the whole. It may be true, as she says in the preface, that no one person can write about the complexities of the health visitor's work, but a better selected and more disciplined group of contributors could produce a unified book about them.

ANDREW SMITH.

Middle Articles

IS THERE AN ALTERNATIVE?

The possibility of a large extension of private insurance schemes for health in Britain has often been raised. What schemes are already in existence, in Britain and elsewhere? What problems would be involved in applying them more widely? What are their advantages and disadvantages? In his article Mr. Arthur Seldon discusses the answers to these and some other questions.

Prospects for Private Health Insurance

ARTHUR SELDON*

Brit. med. J., 1967, 3, 166–168

Insurance, private and voluntary, is increasingly discussed in Britain as an indispensable method of paying for health services at rising standards because it would introduce additional finances not otherwise available for higher payments to doctors, nurses, and administrators; larger expenditure on treatment, training, and research; and increased outlay on equipment, buildings, and land.

Private insurance could supplement the three other methods of financing medical care—namely, fees, taxation, and charges. Firstly, fees for some services will be increasingly practicable for more people as incomes rise. Secondly, the belief that taxation, with the compulsory national insurance contributions that are more a tax than a premium, will yield the required growing sums is fading.[1] To satisfy Professor Henry Miller's eloquently argued proposal[2] that £500 million more would have to be found almost immediately from taxation to give medicine in Britain "the relative priority" it enjoys in the United States—that is, to raise expenditure on the N.H.S. from around £1,500 million to £2,000 million—the Government would have to raise tax revenue by a much larger amount, perhaps by £1,500 million, since it could not allocate £500 million more to the N.H.S. and nothing more to State education,[3] school welfare services, housing, pensions, family allowances, unemployment, disability and sickness benefits, other social benefits, and neglected public services such as the police. Even if national income grew by 3% a year, which is not yet certain, tax revenue would not rise enough to provide State welfare for the increasing number of dependants, children, and old people, or to remove poverty. Tax *rates* would therefore have to be raised, a policy which diminishing numbers in all parties now think is either economically desirable or politically acceptable.

Politicians in all parties are discussing realistic charges for State health services: not only for medicines and appliances but also for consultation and treatment. Mr. Houghton and Mr. Walden have been most explicit in recent weeks. If charges drew substantial sums of additional revenue into the N.H.S., they might enable it to provide the rising standards of services expected by people with growing incomes, and the demand for private medicine might run down. But the more charges are designed to raise revenue and not only deter over-use, the more they would reduce the gap between the cost of State and independent medical care, and the more they might accelerate the growing demand for private services. (If the choice is between a free N.H.S. and paying the full cost of private medical care, only a few will pay; if the choice is between charges for the N.H.S. and paying for private medical care, more will pay.) Which of these two effects would be the stronger is impossible to forejudge. The economic dilemma of charges is that if they are low they will not draw in much revenue, and the N.H.S. will not improve very much or continue to deteriorate; and if they are at or near the market cost they may encourage private practice and insurance.

Whether charges are introduced or not, and whether they are at nominal or market levels, private health insurance will be able to draw on substantial funds that would not otherwise be attracted to medical care by fees, taxes or charges. Hence the case for examining the scope for private insurance.

Principles of a Practicable Scheme

Private insurance for the costs of consultation, treatment and/or income in sickness is provided for about two million people by the British United Provident Association, the Hospital Service Plan, the Western Provident Association, the Bristol Contributory Welfare Association, Independent Medical Services and several smaller schemes. About four million families (perhaps 15 million people) are insured for supplements to State health services by the Hospital Saving Association and similar organizations that could expand to cover private medicine.

---

* Editorial Director, Institute of Economic Affairs (I.E.A.), London S.W.1.

[1] The reasons, empirical, analytical, and institutional, are indicated in the author's "Which Way to Welfare?" *Lloyds Bank Review*, October 1966. Briefly: expenditure on medical care has been rising faster than income in the U.S.A. and elsewhere but not in Britain; citizens are not prepared to pay as much in taxes for services shared with others as they demand for themselves; taxes are regarded as deductions from income, not as payment for services. The academic analysis is elaborated in a growing literature on public finance and the economics of medical care by Professor J. M. Buchanan, *The Inconsistencies of the National Health Service*, Occasional Paper 7, I.E.A., 1965; Professors John and Sylvia Jewkes, *Value for Money in Medicine*, 1963, Blackwell; Professor D. S. Lees, *Health Through Choice*, Hobart Paper 14, I.E.A., 1961; Professor R. A. Musgrave, *The Theory of Public Finance*, 1959; a doctoral dissertation at the University of Virginia by Mark Pauly; and others. The argument has also been spreading to the politicians: Messrs. Desmond Donnelly (*Hansard*, 9 June 1967, column 1468), Douglas Houghton (*Paying for the Social Services*, Occasional Paper 16, I.E.A., 1967), and Brian Walden (*Sunday Times*, 25 June 1967).

[2] "In Fitness and in Health: A Doctor's View of Medicine in Britain," *Encounter*, April 1967.

[3] The President of the Association of Education Committees said at its conference on 21 June 1967 that state education had to have £550 m. a year for essential improvements.

[4] Arthur Seldon, *Pensions in a Free Society*, I.E.A., 1957.

[5] Discussed in *Paying for the Social Services*.

[6] Mr. Patrick Gordon Walker, Minister Without Portfolio, speaking to a seminar of the University of Cambridge Board of Extra Mural Studies, 18 June 1967.

And a small number are insured by a dozen or so insurance offices for medical costs or income during disability. In all private insurers assemble perhaps £15 million a year in subscriptions and premiums. However much the N.H.S. may be able to supplement its £1,500 million by charges, there would seem substantial scope for tapping the £15,000 million spent on everyday or household consumption.

The experience of private insurance in Australasia, North America, Europe, and even Africa could also indicate lessons and warnings—provided differences in national economic and social conditions are allowed for in adapting methods and machinery. Australia seems to offer examples of insurance schemes with attractive characteristics; schemes adopted in Britain might incorporate some features of Australian schemes and adapt features of schemes in the U.S.A., Canada, Norway, France, Ireland and other countries. At this stage it would seem possible to discern several generally desirable characteristics.

Market Price

All services, State and private, should work towards charging the full market price to cover current and capital costs. It is here—in charging less than market price—that the two main weaknesses, under-supply and over-demand, originate. For a time it may be necessary for the State, centrally or locally, to provide capital at less than market rates of interest. Ultimately, prices or charges should be sufficient to cover capital costs at market rates of interest.

State Subsidy to Consumer

State "subsidies," to replace the insurable parts of the free N.H.S., should be paid not to the suppliers of health services but direct to consumers in the form of cash or vouchers with which to insure for State or private services. There is no problem of the "deprived" who cannot pay or the irresponsible who will not pay. Other health services would continue to be provided by public authority.

Payment By Patient

Payment to the doctor or hospital for individual units of service should be made, so far as is administratively possible, and except in emergency, by the patient—as it has been in France, Sweden, and Norway, not by the insurer—as in Denmark, Germany, and Switzerland. Machinery for rapid reimbursement, or better still prepayment, of the patient would be desirable.

Patient's Fraction ("Deductible")

The patient should bear part of the cost of each bill—a larger proportion of small bills, a smaller proportion of large bills. In Australia the patient's fraction has been at least 10 per cent. In France it has been 20 per cent. (recently proposed at 30 per cent.) and in Sweden 25 per cent. The "deprived" would pay less or nothing. An income coding to yield a reverse tax—i.e., an automatic supplement to low incomes, discussed in principle by the American economist, Henry C. Simons, advocated in Britain for at least 10 years,[4] persuasively urged by Mr. Houghton recently,[5] and now examined by the Government,[6] would identify people with low incomes, mostly pensioners but also heads of larger families and others, to whom the State could return the patient's fraction as expeditiously as private insurers the amount covered by insurance.

Specialist or Composite Insurers

There could be specialist or composite insurers for (*a*) costs of general-practitioner consultations, medicines, and treatment; (*b*) specialist consultation; (*c*) hospital treatment; and (*d*) income during disability.

State as "Long-Stop"

Private insurers would cover a growing range of risks (in Switzerland poliomyelitis has been added), but some claims for long-term treatment for physical or mental ailments might have to be reinsured with the State as "long-stop."

Competition

Insurers should be both mutual and commercial, profit-making and non-profit-making, State (but not subsidized) or private, provided they satisfy State standards. The aim should be to facilitate competition so that the schemes with lowest costs and highest consumer preference can be discovered.

Experience Rating

Insurance premiums would probably emerge as a mixture of "community rating" (average for varying risks) and "experience rating" (refined to the risks of individual groups) according to the size of the insurers, the degree of competition, and the form of State subsidy as producer or consumer subvention. "Community rating" in a private scheme may be essential or desirable in a small or growing country, but in operating a "private welfare state" the organization may be vulnerable to State influence or control. The danger has been avoided in Australia but it might not be in Britain.

Publicity

Insurers should be encouraged to advertise their schemes by any means allowed under law. If health insurance is desirable there should be no inhibition in publicizing the premiums and benefits of individual schemes.

Compulsory Insurance?

Since 95% of people in Britain have never experienced voluntary insurance for private medical care it is arguable that private insurance should be compulsory for an initial period of five to seven years. Thereafter it could be voluntary, as in Denmark and Australia.

Advantages

The advantages and disadvantages of a scheme of private insurance as outlined, particularly the voucher component, could not be learned until it is established. Results observed in other countries might not be reproduced in the sometimes dissimilar British setting. The general assumptions made by economists about human motives, administrative organization, and the working of markets suggest a number of advantages:

Private insurance would go as far as is feasible to take medicine out of politics. The State would continue to provide environmental paramedical services; it would require preventive consultation and treatment; it might provide personal services—for fees or charges—in competition with private services, as it now does in transport and fuel; and it would finance consumers by vouchers, reimbursement of "patients' fractions," and the full costs of long-term treatment. But the doctor and the hospital would be paid by the patient for the mass of medical care.

Patients and doctors would know the full costs of the services they bought and sold. The tendency of patients to over-use free or partly free medical services and of doctors to over-prescribe for importunate patients would be checked.

The maximum practicable choice of doctor by patient and patient by doctor would be facilitated. The doctor–patient relationship would become more flexible. Doctors could vary charges according to individual and local circumstances. Less satisfactory doctors would go out of practice. More troublesome patients would pay more.

Private insurance financing would strengthen the independence of the general practitioner. Technical advance will continue to make medicine more "scientific," but social advance will stimulate the expectation of personal service, attention, consideration, choice, timing, convenience, and comfort. And these are largely the province of the general practitioner.

Doctors and patients could make any of a wide variety of arrangements they prefer. Doctors could organize themselves into loose federal arrangements for payment by capitation, case, period (salary), or unit of service.

The transformation of every patient, irrespective of original income, except the mentally or otherwise incapable, from a "beneficiary" into a buyer armed with purchasing power would remove the social divisiveness of a system in which—as now in Britain—the few pay for private services and the many receive a free State service.

Choice, competition, and variety would stimulate voluntary addition of purchasing power to the voucher. The underlying technical standard of medical care would rise as salaries and fees rose, equipment and buildings were improved, and new health centres and hospitals were built; but there could be as many standards of personal service as people were prepared to pay for.

In time independent training and research institutions could be established to diminish the risk of error resulting from the over-centralization of Government forecasting, recommendation, and decision. A repetition of the 1957 Willink error would be less likely.

Disadvantages

The main disadvantages or risks of private insurance would appear to be the following.

Administrative costs would probably be higher—8 per cent. or more—than in a centralized State system—5 per cent. or less. Doctors and hospitals would be paid by hundreds or thousands of patients instead of by one State department. Servicing costs are necessarily higher for a personal than for a standardized service. Moreover, the uncertainty of doctors' income would increase, but this is the obverse of the coin of independence.

The bulk of the patient's payment would be by annual premium out of income supplemented by State cash or voucher unrelated to a specific unit of medical service at the time it is received and experienced. Indirect payment at second hand is a second best to direct payment at first hand as a means of inducing patients to think twice before using a doctor. Indirect payment by annual premium divorced from individual bills also weakens the discipline on medical fees and medicine prices. Complaints of increasing costs outrunning insurance benefits are common or frequent in the U.S.A. and elsewhere. Doctors can alienate the goodwill of the public on whom their livelihood depends if they appear to act as an organized trade association. The remedy is commonly a State schedule of fees and costs; but it may tend to be inflexible and to invite political influence. A better remedy would be competitive pricing by individual doctors and hospitals, perhaps required by a general law against collusive restrictive practices, and possibly larger "deductibles" for smaller bills so that patients would be more sensitive to increases in fees.

Selling costs would be higher than in a uniform State system; but competition would encourage improvement. Voluntary insurance in Britain has low selling costs but also a slow rate of expansion. Field studies conducted for the Institute of Economic Affairs and B.U.P.A. suggest that far more than two million would have become subscribers by now if private insurance had been publicized more thoroughly.

Initiation of General Private Health Insurance

Health insurance may spread rather faster in the next few years now that there is a little more marketing effort and competition between B.U.P.A. and its smaller competitors. But even if the annual rate of expansion were 20 per cent, it would be 1971 before the number of subscribers rose to 4 million—still only 8 per cent. of the population. Health insurance could be sold by "mutual" and commercial insurance underwriters and brokers. Private beds could be made available in State hospitals, and new private hospitals and nursing homes could be built with endowed and/or commercial capital. The blockage is not so much in supply as in demand. There is no shortage of men or women to train as doctors or nurses, or of bricks, concrete, steel, wood, or glass to erect buildings and equip them with wards, kitchens, and operating theatres. Supply would appear as if from nowhere if the demand were created.

The demand could be stimulated by income tax rebate on insurance premiums or fees—as in Australia and Ireland—or by notional rebates to everyone, income-tax payers or not. But in Britain these methods would probably be too slow, and a more fundamental, dramatic method is required. State payments direct to the consumer, in cash or preferably in vouchers, are the prerequisites for a rapid growth in private health insurance to pay for competing State or private services.

The voucher principle is simple in essence.

Instead of a free State service everyone would have a coupon with which to insure with the medical insurer and service of his choice. If the State hospital service costs £20 per head a year, the "hospital voucher" could be, say, £15 per head to insure for most forms of treatment, leaving £5 with the State to cover long-stay, abnormal maternity, mental and geriatric treatment. If general practitioners cost £3 a head and prescriptions £3 10s., the "family doctor voucher" could be £6 10s. Dental and ophthalmology service could be paid in cash, with remission by income code (although B.U.P.A. insures orthodontic treatment). Local health services, which may cost £4 a head, would continue to be financed out of taxes, unless they could be provided more efficiently by private suppliers.

Vouchers could be varied with income by being taxed: they could vary with regional hospital costs; they could differ for children, adults, and the over 70s.

If people are prepared to pay more for better food, clothing, furnishings, motoring, holidays, it should be possible to enable them to pay more for better medical care. In 1965 23% of a sample of 1,660 people aged 16 to 65 said they would accept a £5 voucher per head of the family and add £5 to pay for private health insurance costing £10 a head; in all they would add £45.4 million. In time it is reasonable to suppose that experience, competition, and rising incomes would raise the amounts added to the voucher out of current expenditure on everyday household consumption.

SELF-HELP IN THE HOSPITALS

St. Christopher's Hospice

[FROM A SPECIAL CORRESPONDENT]

St. Christopher's Hospice dates its foundation from the first gift—left in 1948 by a young Pole who died of cancer in a ward of 50 patients. He discussed with the almoner the possibility of establishing a small institution for patients with problems such as his, and when he died he gave £500 to provide a window if such a home was built. Since then almost half a million pounds has been raised for St. Christopher's Building Fund Appeal. The first stage of the hospice is nearing completion; it will have received its first patient by the time this article appears. The young Pole's window round the front entrance stands out among the many parts of the building that are named for particular gifts.

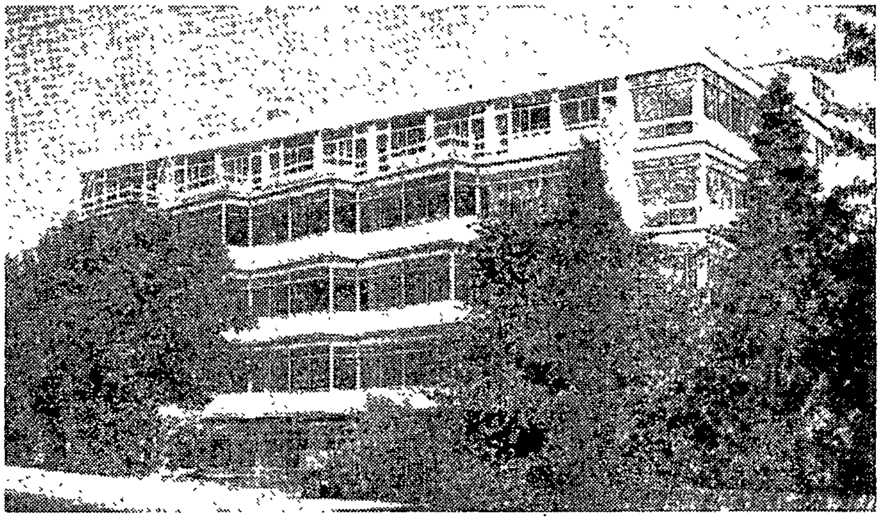
Aims of the Hospice

St. Christopher's Hospice is planned, as its Medical Director, Dr. Cicely Saunders, once said, "as something between a hospital and a home—combining the skills of the one with the warmth and welcome that belong to the other." It will care for people in pain and distress who cannot be cared for satisfactorily at home. Many of them will be the terminally ill, with a prognosis of no more than three months, who will probably spend the last weeks of their life at the hospice; others will be admitted with long-term illness and chronic pain and are likely to stay much longer. Both types of patients may be enabled to return to their homes. An outpatient clinic and an experimental domiciliary service will become part of the work of the hospice.

The basic aim of the hospice is to give these patients a real chance to live their lives, short or long, as fully and as peacefully as possible. Moreover, the hospice also has a broader aim—it wants to stimulate the growth of skill and interest in the care of these patients. Research and teaching will therefore be one of the prime functions of the hospice from the beginning. It will, for example, carry out further work into the relief of pain and distress, believing that this must include the understanding and treatment of mental as well as physical pain and also of all the other discomforts of such illness.

St. Christopher's is a religious foundation of an unusually broad character and it is difficult for such a foundation to retain its essential character as part of a public service; that is why it will remain an independent body. This independence will also help the hospice to remain freely adaptable to new ideas and to pioneer effectively in this new field. From the beginning this has been discussed with the Ministry of Health and the regional hospital board, and contractual arrangements have been made with the latter, so that for most of the patients care will be free.

Late in 1962 a suitable site for building the hospice was found in the London Borough of Bromley. The committee did not know the exact cost of the project at this stage—only that it would amount to some hundreds of thousands of pounds and that this could be raised only from private sources, both from the large charitable foundations and from individual donors. In fact financial help had been promised a year before the site was found, the City Parochial Foundation having promised a grant of £50,000 when developments assured the establishment of the hospice. The first grant actually paid to the hospice came from the King Edward's Hospital Fund for London, which gave £27,000 and the expenses involved in purchasing the site in 1963.



St. Christopher's Hospice.

In March 1964 the St. Christopher's Hospice Building Fund Appeal for the first stage of building was launched with "The Week's Good Cause" appeal on the B.B.C. Home Service. Shortly afterwards the Drapers' Company promised £50,000 for the old people's wing, and without this grant the latter could not have been included in the first stage.

In December 1964 the Nuffield Foundation granted £60,000 for a ward and the Sembal Trust £22,680 for a section of a ward. A legacy from the U.S.A. enabled a second site near by also to be acquired. To date over £400,000 has been received for the hospice, and only about £70,000 is still required to complete and equip the first stage of the building.

A Local Appeal

In 1967 the London Borough of Bromley set up a local appeal committee to raise money locally. The appeal was officially launched by the Mayor in February 1967 at a public meeting in the uncompleted building. Bromley people have organized their fund-raising functions to contribute to this appeal, while, in addition, those interested are beginning to form the nucleus of a volunteer department, which will help to make the patients feel part of the local community. Some of the several hundreds who already comprise the Friends of St. Christopher's Hospice will be joining them in what it is hoped will develop as an integral part of the work of the hospice.

The first stage of the building includes: ward accommodation for 54 patients, together with very ample day space and facilities, the Drapers' Wing for 16 elderly people, some staff rooms, and the outpatients' clinic. The ward block will finally accommodate 75 patients; the regional hospital board will have contractual arrangements for 40 of the original 54 beds, and these will therefore be free to patients. Money will be raised in various ways for the other patients and residents.

The hospice illustrates very forcibly the important and valuable part that voluntary institutions can still play in a country whose medical needs are almost entirely met by a State service. The practical realization of the vision for St. Christopher's demonstrates also how by hard work and dedication very large voluntary projects indeed can start from the smallest beginnings and come successfully to fruition even in these supposedly complacent days of the Welfare State.

Radio Communication and the Emergency Department

M. H. HALL,* M.R.C.S., L.R.C.P.; R. S. GARDEN,† M.B., M.CH.ORTH., F.R.C.S.ED.

Brit. med. J., 1967, 3, 170–171

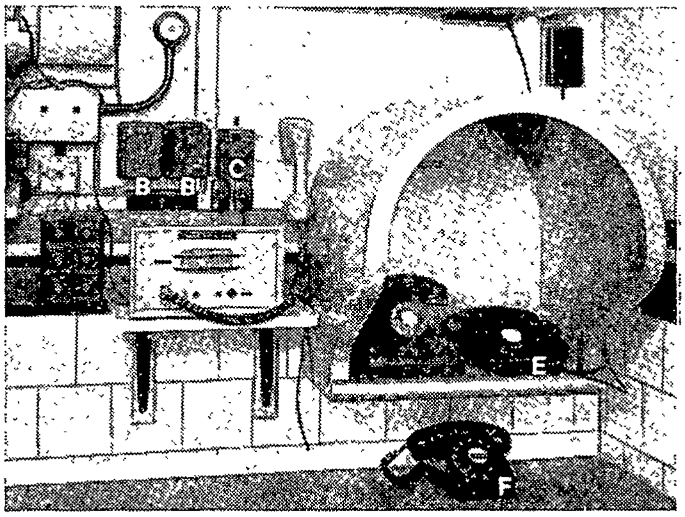
Several years ago it was decided to investigate the use of radio communication between the Emergency Department and the ambulances serving the Preston Royal Infirmary (Garden, 1962). The telephone line already existing between Lancashire County Council ambulance headquarters and the hospital was used to complete the radio link, but technical problems arising from the length of the land lines caused some delay in the early stages. Improvements made by the radio department staff of the Lancashire County Constabulary, however, enabled the ambulance headquarters operator to monitor the signal and switch from transmit to receive as required. At the hospital the telephone line terminating in the ambulance officers' room was extended into the Emergency and Accident Department (Fig. E). An ordinary bell-push beside the telephone in the ambulance officers' room was installed to ring a warning bell in the emergency department when an ambulance attendant wished to communicate by radio with the medical officer on duty during the day (Fig. A). At other times an indicator relay worked by the telephone circuit was used as a warning device (Fig. B).

This experimental arrangement proved to be of immediate value in alerting the hospital staff of the impending arrival of seriously ill or injured patients, and in maintaining contact between the hospital and the flying squad dealing with motorists or workmen trapped as a result of road or industrial accidents.

The Emergency and Accident Department is extremely cramped; over 30,000 new patients are treated annually within a total floor area of only 956 square feet. During a large part of the day there is little unused space, but the information that a seriously injured patient is on his way to hospital allows time for room to be made available and resuscitation equipment to be set out. If several patients are expected, confusion and delay in treatment are avoided by calling extra help to the department before the patients reach the hospital.

It soon became apparent that if advantage was to be taken of this early warning it was essential to set out full resuscitation equipment before each patient arrived. This required the design of new types of equipment and the development of fresh methods of instrument storage to overcome the inherent difficulties under which the department is required to work.

Because the results of this initial experiment were so successful, radio-link facilities were extended to the Borough ambulance vehicles, using a remote-control unit installed in the Emergency Department (Fig. D). This unit was connected to the tie-line between the hospital and the Borough ambulance headquarters (Fig. F), the telephones being disconnected from the tie-line by a switch (Fig. C) when the radio link was in operation. This arrangement proved easier to operate than the County system, because the send-receive switch was incorporated in the handset of the control unit. Warning devices similar to those in use for the County system were installed for use during the appropriate hours (Fig. A^1, B^1).



The radio-link installation. A, County, and A^1, Borough daytime warning bells. B, County, and B^1, Borough nighttime indicator relays. C, Radio/telephone switch for Borough system. D, Remote control unit for Borough transmitter. E, Tie-line telephone to County ambulance headquarters. F, Tie-line telephone to Borough ambulance headquarters.

To ensure that all members of the staff are able to use the equipment a short test transmission is made every morning. This has proved helpful in overcoming the strangeness felt by most people using radio communication for the first time.

Results

One of the most gratifying and highly welcome by-products of the early warning system has been the unexpected competition that has arisen between the ambulance personnel and the departmental staff to ensure immediate attention for seriously injured patients.

It has clearly emerged that the avoidance of even a minute's delay in starting resuscitation can preserve lives which even a few years ago would have been lost. As an example, 97 patients suffering from severe multiple injuries have been treated in the department during the past three years. Of these patients 68 had sustained crush injuries of the chest and 32 showed paradoxical respiration. The overall mortality was 20%, and many patients who were in extremis on arrival would certainly not have survived if the department had been inadequately equipped or unprepared for the immediate relief of respiratory embarrassment.

---

* Senior Accident Officer, Preston Royal Infirmary.

† Consultant Orthopaedic Surgeon, Preston Royal Infirmary; Lecturer in Clinical Orthopaedic Surgery, University of Liverpool.

Discussion

Apart from its value in the management of trauma, the radio link enables advice to be given direct to the ambulance personnel. This facility is greatly valued, as they no longer feel cut off from medical aid when faced with difficult problems, especially during the transport of seriously ill or injured patients to the Accident and Emergency Department. On occasion it is tempting to shorten the journey by taking the patient to the nearest hospital, but this is not always in the best interests of the patient, and radio contact with the accident centre can help to relieve the anxiety of the ambulance personnel in these circumstances.

Abuse of the flying squad is prevented by avoiding call-out when the information received over the radio link makes it clear that little or no benefit can be expected.

The radio link enables the most efficient use to be made of the available nursing staff during the night, because the senior nurses can continue their normal duties in other departments and need not be summoned to the emergency unit until the patients are expected to arrive.

When the emergency team is summoned to an accident messages can be sent back to the hospital with information about the patient's condition and the estimated time when he is likely to be brought to the hospital (Hall, 1965).

> The emergency team was called out at 4 a.m. to deal with a lorry driver trapped in the cab of his vehicle after a motorway accident. A message was sent to the hospital stating that his release would take a long time.
>
> Subsequent messages asked for two pints (1.14 l.) of Group O Rh-negative blood to be sent to the scene of the accident. A transfusion was begun while the driver was still trapped, and a short general anaesthetic was needed before he could be extricated at 6.30 a.m. A message was then sent with the information that the patient would reach the hospital in 30 minutes' time.
>
> Because the patient was receiving a blood transfusion, and because his fractures were immobilized, a slow and steady journey to the hospital was possible. There was no need for haste, and when he arrived in the emergency department his condition was appreciably better than it had been when he left the scene of the accident.

Future Developments

The radio link at Preston Royal Infirmary operates over the normal telephone cables, but this is not necessarily the best arrangement under every circumstance. The use of a radio transmitter under the department's control would provide additional facilities, although tie-lines would still be needed to avoid constant monitoring by the hospital staff (Collins, 1966). A transmitter with several channels would allow the department to contact direct not only the ambulances but also the police and fire services. This would be helpful on many occasions, and discussions are now being held with a view to the acquisition of suitable apparatus. Adjacent ambulance services, using different radio frequencies, could then contact the hospital during the transference of, for example, neurosurgical patients coming for treatment from hospitals some distance away. Should the condition of these patients cause anxiety, direct contact with the receiving hospital would permit advice or active help to be given during the journey. Unfortunately this is not generally practical at the present time because of the widely differing frequencies and types of modulation used in the radio installations of various ambulance authorities. It is hoped, however, that the committee now considering the equipment of the ambulance services will make recommendations which will enable a standard type of communication set to be used in emergency departments throughout the country.

Experiments are now being undertaken to transmit electrocardiographic information by radio link from the ambulance. If this proves to be practicable it will allow monitoring of the cardiac state of patients with severe injuries or collapse after coronary thrombosis, and by giving advice to ambulance personnel the survival rate, especially from coronary infarction in the younger age groups, might possibly be increased.

Messages from a mountain rescue team several miles away have been relayed directly into the emergency department, and there is no obstacle now to the provision of similar facilities for air-sea helicopters or other rescue services. Indeed, it is only by enabling all rescue services to collaborate at an early stage that significant advances will be made in the treatment of casualties before they reach a hospital. With this in mind, it would seem logical that the allocation of a common national rescue radio-frequency should be considered by the General Post Office.

Little thought has been given in the past to the care of patients before they reach hospital, but the attention of the ambulance services has now been drawn to this deficiency (Working Party Report, 1966). Emergency departments should likewise appreciate the expanding part they have to play in this direction. Although the next ten years will doubtless see an expansion of the facilities for the early management of the seriously injured greater than has ever occurred before, the ideal of medical help for the patient from the moment of injury will remain a physical impossibility. An adequate communication network, however, will at least ensure that medical advice is available at the earliest possible moment.

We wish to acknowledge the enthusiastic help we have received from the staff of the Preston Borough and Lancashire County Council ambulance services and the radio department of the Lancashire County Constabulary.

WITHOUT PREJUDICE

A friend sent me the other week a copy of an address given to the Wigan Division of the B.M.A. in April this year by Sir Harry Platt, a youthful octogenarian. The title of his talk was "Medicine and Authority"—full of vigour and wisdom. He asked at the end of his talk the question whether the doctor of the future would remain a man of authority and independence. Both are being challenged in more than one country. "I have no doubt," Sir Harry said, "that the education and training of the doctor during the last fifty years, throughout all its changes, turned him out as a man of affairs well able to face the contemporary problems of society. . . ."

There must have been a lot of virtue in our medical community during this century. The training and education doctors received were thorough, the standards they set themselves and set others were remarkably high. They made great contributions to clinical medicine. And they engaged in public life while still active in their profession. Medicine seems to attract a good share of such men. I think the biologist is probably more versatile, more adaptable than other scientists. And as a scientist the medical man is a biologist, a student of human biology. In this capacity he has much to give the community in which he lives. The late Lord Brain was a remarkable example of the medical man in authority in the society in which he lives. And then there is Sir Arthur Porritt, a youthful surgeon now approaching his 67th birthday, soon off to New Zealand as its Governor-General, the first medical man, I believe, to be appointed to such a great position of trust.

I often wonder whether the new kind of authoritarianism in Medicine that seems to be the underside of our State medical service will stunt the growth of the independent mind that is such a valuable feature of the professional man at his best. It is something society can ill afford to lose in a world of shifting values.

"In all countries where highly organized health services have become the direct concern of central government," Sir Harry Platt says, "the doctor, irrespective of the source of his remuneration, must now fight to retain his position as an independent leader and adviser." I believe that the independence and resourcefulness of the outstanding men in our profession during, for example, the present century were very much part of their way of life as private doctors who have had to fight their way up with courage, initiative, hard work, and a competitive thrust to excellence. If the sole source of remuneration for the doctor is the State, then Sir Harry's fight will be a hard one. The State does not like too much independence in its servants.

* * *

I have just been looking through the volume *Fifty Years of Medicine* brought out by the *B.M.J.* in 1950. What a remarkable and magnificent story it is! What we inherit today is the result of the pioneering work of men who grew up in the much harder world of free enterprise. We owe a great deal to them, and should not underestimate our inheritance.

Just look at the picture the late Professor G. Grey Turner painted in the *B.M.J.* symposium! What an advance the old pioneers—as they must seem to us now—made and in what circumstances! Some measure of their difficulties, and of the distance we have moved since 1900, may be gauged from Grey Turner's description of surgery in his younger days. Operations were often enough carried out in most difficult circumstances in the patient's home. Most surgeons, Grey Turner says, took little equipment with them. Most of it, or all of it, would go into a Gladstone bag. A baking bowl from the patient's kitchen would serve as a "reservoir for Lister's strong mixture in which to soak towels clean from the wash. . . ." A meat dish served as an instrument tray.

Illumination was a hazardous affair of lamps and candles. "No one knows," wrote Grey Turner, "how feeble is the light from candles unless he has tried to do a strangulated hernia or remove an appendix with its aid." And when he was recollecting his experience for the *B.M.J.* symposium, published only 17 years ago, he remarked, "In retrospect I am prepared to reiterate that I have not yet seen the surroundings in which I could not operate with assurance, provided always that I personally superintended every detail of the arrangements."

* * *

I think that in decency we might recall the virtues of private practice before we exorcise it with bell, book—and candle. It had its bad sides, and these are the only sides the "Statist" can see. But the stimulus was productive of excellence. In his *Lancet* article last year Henry Miller said of the generation of neurologists just retired from hospital practice that a number were physicians of international stature, "well able to stand comparison with their great predecessors of the nineteenth century." He paid a neurologist's tribute to them. "In the intervals of exacting hospital work, undergraduate and postgraduate teaching, and busy private practice, they made major contributions to the study of the nervous system and nervous diseases. To these outstanding individuals the milieu in which they worked was a stimulating one, and it is improbable that any would willingly have abandoned it to become full-time academic physicians."

But Miller is surely right in seeing the future bound up with the establishment of academic units of clinical neurology "closely integrated with internal medicine and with the laboratory departments" if it is not to be left behind in the race for excellence.

There was a lot of truth in Clifford Allbutt's saying, made I believe at the Cambridge meeting of the B.M.A. in 1919, that Harley Street was the graveyard of clinical research. Private specialist practice is to all intents and purposes out in the Scandinavian countries, and surgeons I have talked to there would not have it back.

* * *

It is economics as much as anything else that has forced the change of direction. And it is economics that will determine the growth and development of Medicine in Britain. Sir Harry Platt, in his Wigan address, made an effective plea for reinforcing the State contribution by active voluntary contribution. He noted that in the U.S.A. and Canada the success of this depended "on the existence of an intelligent tax system whereby modest annual contributions are tax free, and large gifts are immediately free from estate duty." Surely we might imitate what appears to be a good model!

In the U.S.A. I was interested to learn from the *New England Journal of Medicine,* third-party payments, in 1964, met 82% of all costs for hospital care, most of it coming from insurance. And the author of the article, Professor Somers, estimates that some 43% of the cost of services of the physician in private practice was also met by third-party payments—from private insurance, combined with payment from governmental agencies. He sees Medicare as a stimulus to private insurance, and the two of them as being mutually supportive. "In short," he says, "the years ahead will witness a massive increase in both public and private financing of health services, although the public portion will be greater. The nation [U.S.A.] is now committed to assuring that all medical needs will be met and paid for."

We reached that decision twenty years ago. We have now got to tap private sources of money in order to keep the pledge. The public must put its hand into its private pocket to make the N.H.S. a success by contributing to it directly as well as through taxation. In this way the public would show that it really believes in the N.H.S., and wants it to prosper.

Nature of the Scrapie Virus

SIR,—It has recently been suggested[1, 2] that scrapie—a transmissible disease of the central nervous system in sheep, goats, and mice—may be related to multiple sclerosis, and so a study of the nature and mechanism of action of the infective agent of scrapie could be important in the understanding of the human disease. A similar pathogenesis may also be attributed to other obscure degenerative diseases of the central nervous system in man, one of which, kuru, has recently been transmitted experimentally to chimpanzees.[3]

Although many of the properties of the scrapie agent are consistent with the supposition that it is a slow virus, there have been many reports of its exceptional stability to the action of heat, ultraviolet and *x*-irradiation, chemical agents such as formalin, and enzymes. There is also a growing body of evidence suggesting that the scrapie agent is of extremely small size, perhaps as small as 3 mμ,[4] and that the infection does not result in the production of antibody by the host.[5]

Recent evidence, particularly that concerning its stability, has led to speculations that the scrapie agent may represent a new class of replicating particles.[6] Its resistance to irradiation led Alper and her colleagues[7, 8] to suggest that the scrapie agent might be a replicating particle not containing nucleic acid; Pattison and Jones[9] proposed that it might be a histone, while Field[2] mooted the possibility of its being a replicating polysaccharide.

However, it seems to us that such radical departures from conventional virus theory are not essential to explain the many exceptional properties of the scrapie agent if certain assumptions are made concerning the nature of the viral coat. Although it is generally assumed that viral nucleic acid is sheathed with protein (possibly mixed with some lipid), there appears to be no a priori reason why this should invariably be so. We would like to suggest tentatively that the scrapie agent consists of a small nucleic acid core enclosed in a mucopolysaccharide or even polysaccharide coat, and further that the nucleic acid core is stabilized structurally by covalent bonds with the sugar residues in the coat. Such a model might be expected to be very resistant to energy disruption, to be weakly or non-antigenic, and to carry enough coding information even with a relatively small nucleic acid core for the small amount of protein which may be present in the coat structure.

Further detailed considerations of a theoretical model are in progress and attempts are being made to obtain experimental verification of this hypothesis.—We are, etc.,

Future of Mental Hospitals

SIR,—Your leading article on the future of the mental hospitals ends on a very gloomy note (24 June, p. 781). It suggests that there is no alternative between the "living graveyards for increasing numbers of senile patients and repositories of . . . 'long-stay' schizophrenics" and the social chaos which might occur if the older mental hospitals suddenly disappeared.

You seem anxious to justify the retention of the old mental hospitals and the system they represent. The fact that there is variation in bed needs from area to area hardly undermines the thesis that the total bed numbers will be reduced, nor does the unfortunate fact that there are insufficient community facilities available alter the need to plan for a future when such facilities will be available. Hundreds of patients still in mental hospitals do not need to be there. In the case of many patients they share the attention of one nurse with fifty others, see their doctor once a year for a routine annual examination, and may have no medication whatever and the most elementary daily routine. These patients may indeed need some measure of supervision and accommodation but it can hardly be claimed that they are having *hospital* care now or, indeed, need this level of provision. The old mental hospital service was intended to isolate and institutionalize and it did this very successfully with large numbers of inadequate people.

No one wishes to see social chaos, any more than most psychiatrists can feel contented with our present "living graveyards." Like many others, I had thought that we were planning for a future where the patient needing admission and treatment would be treated within the acute general hospital system, while the longer-stay patient needing nursing care and rehabilitation would be treated in the longer-stay hospital, catering for the longer-stay patients from medicine, neurology, and other specialties. There seems no good reason for providing a separate mental hospital, any more than there are good reasons for providing a separate hospital for patients with rheumatic disorders, for example. Many patients have multiple disabilities, particularly the more chronic patient and, as studies have shown, to attempt segregation of patients is usually to the detriment both of those who have psychiatric disabilities with a physical accompaniment and the many patients who have physical disabilities and some psychiatric accompaniment.

The patients staying on in mental hospitals tend to be those who are unwanted by the outside community. Whether they are unwanted is often unrelated to the severity of their illness. It is very rare to find a beautiful woman on the back wards of a mental hospital. It is to be hoped that our society, which is gradually coming to understand the problems of the mentally ill and showing a greater willingness to tolerate and accept these patients, will not replace them with the geriatric patient, who suffers just as much by being rejected and isolated away from their home community as the psychiatric patient. Neither the schizophrenic nor the senile patient wants to end his days in the "living graveyard."—I am, etc.,

Banstead Hospital,
Sutton, Surrey.

Trismus Following Inferior Dental Nerve Block

SIR,—A considerable number of cases of severe trismus have been seen recently which followed inferior dental nerve block injections. In most instances local analgesia had been given merely to carry out conservative dentistry procedures, such as fillings, and not in order to perform surgery. According to the operators the injection was painless and uneventful, but later a progressive trismus developed over a period of three or four days, resulting eventually in complete inability to open the mouth.

On examination of such a case no tenderness or swelling is present and the only physical sign is extreme limitation of opening. Gentle pressure on the mandible gives a feeling of mechanical locking of the jaw and causes slight pain in the region of the medial pterygoid muscle. No improvement in mouth opening occurs with the passage of time, and in one instance the limitation of jaw movement had been present for three months. However, once established the condition does not appear to deteriorate. Active jaw opening exercises achieve little improvement and there is no relaxation of the masticatory muscles upon giving a general anaesthetic.

If the mandible is gently prised open under general anaesthesia, using a mouth gag between the teeth on either side of the jaw, a characteristic cracking sensation is detected in the region of the medial pterygoid muscle as the impediment to movement is overcome. Following this action normal mouth opening is restored. The patient does not experience any postoperative pain and there is no tendency to recurrence. Care must of course be taken not to exert excessive force when opening the mouth in this manner, and a wide-bladed instrument, such as a Featherstone gag, should be used in order to avoid damage to the crowns of teeth or the accidental displacement of an upper second premolar into the maxillary sinus.

The cases examined appear to have had no common aetiological factor in so far as the injection technique and the nature of the analgesic solution is concerned. The most likely cause appears to be that with the modern, thin, sharp hypodermic needle there is a greater risk of penetrating a small artery. Rupture of the vessel would then cause haematoma formation with subsequent organization of a band of fibrous tissue in the vicinity of the medial pterygoid muscle. This would explain the gradual onset of the trismus and the mechanical locking effect achieved, and also account for the recent increase in the condition.—We are, etc.,

Guanoxan

SIR,—We were interested to read the paper by Dr. V. Vejlsgaard and his colleagues (3 June, p. 598) in which they reported a double-blind trial of four hypotensive drugs. One of these drugs, guanoxan, we have used in an extensive clinical trial for more than two years, and the results of this trial are soon to be reported in detail elsewhere.[1] In our series we also found that severe lassitude is an important side-effect in some patients on guanoxan.

Vejlsgaard remarks that they found no evidence of a hepatotoxic effect of guanoxan. We would suggest that this was partly because in their trial the number of patients was small and they were observed for a short period of time (40 patients observed for from two to six months). In our trial we had 96 patients observed for periods from 2 to 27 months; 54 of these patients were observed for over one year. In our series 26 patients (27%) had some derangement of liver-function tests at some time and 10 patients (10%) had severe abnormalities of their liver-function tests—that is, very high serum transaminases with raised serum alkaline phosphatase. Four of these 10 patients developed frank jaundice and one of the four died with acute on chronic hepatic necrosis. Further details of these cases will be published.[1]

Since our trial was officially closed further cases of liver-function-test abnormalities have occurred among the patients who remain on the drug. One of these patients had severe derangement of his liver-function tests. We do not claim that the incidence of abnormalities in liver-function tests that occurred in our trial is necessarily the true overall incidence, but we do think that it represents a fairer picture than that of Dr. Vejlsgaard's trial, as the occurrence of liver-function-test abnormalities from patients on guanoxan in other centres has been at roughly the same level as in our trial, as reported in your correspondence columns (14 January, p. 111).

Finally, we would also like to draw attention to the fact that a systemic lupus erythematosus syndrome has also been observed in patients on guanoxan. One such patient was reported in the letter referred to above and a further case is reported in our paper.—We are, etc.,

Lead Absorption in Children

SIR,—We have read with interest the paper by Dr. N. Gordon and colleagues (20 May, p. 480) on lead absorption in children, with particular reference to its association to mental retardation. In that paper it is stated that we claimed that "lead was a greater factor in producing mental retardation than previously thought" and that a "raised blood lead level is a common finding among mentally retarded children and that this is of aetiological significance." It is true to say that in comparison with our own control group, in which the upper limit of normal for blood lead was 36 μg./100 ml., 55% of the mentally retarded children did have elevated blood lead values, but it was never at any time claimed that this was of primary aetiological significance so far as the mental retardation was concerned, and thus Gordon and his collaborators are quite mistaken in their assertions. What was claimed, and this was the whole point of the paper, was that mentally retarded children with pica (to which many are prone) are clearly more liable to lead poisoning if there is lead in the environment, and in such circumstances the neurotoxic effect of lead could further impair their functioning.

The authors also assert that we claimed improvement with treatment of a child with a blood lead of 48 μg./100 ml. on clinical grounds alone. Again, this is a misrepresentation of our statement. The improvement was assessed clinically and also by formal psychometric assessment as detailed in the paper.

During childhood, the detection of lead poisoning before clinical toxicity is apparent still remains a difficult problem. It is not unreasonable to assume that lead can interfere with intermediary metabolism long before the classical clinical symptoms are produced. The choice of normal subjects is always difficult in clinical medicine, particularly in paediatrics. It is surprising that Gordon's controls included children that, by any standards, had significantly elevated blood lead values and that these children showed no signs at all of toxicity. It is also surprising that the authors found such variability in levels of repeated examinations.

Our original plea was not that lead poisoning caused much more retardation than was generally thought, but that mentally retarded children who have pica and who ingest lead could possibly deteriorate even further. It remains our considered view that the clinicians should do their best to detect and treat lead poisoning before the onset of severe symptoms. It is important that the parents should be aware of the dangers of pica, especially chewing paint in old houses. It may be that we will never know at what level lead becomes actively toxic until we have an accurate test of a biochemical nature to assess this.—We are, etc.,

The Scabies Epidemic

SIR,—As Service dermatologists abroad we see a small but constant number of cases of scabies, but certainly not the epidemic proportions described in your pages as occurring in Great Britain (18 March, p. 669).

I was impressed on returning to Britain after two years abroad by the vast increase in the number of youths wearing long hair, to which syndrome is usually added a failure to wash. The present-day soldier, whether he likes it or not, is obliged to wash regularly and keep himself smart, which I believe is one reason why the scabies epidemic has not affected the Services in my own experience.

Lack of precise instructions on the use of benzyl benzoate is no doubt another cause of failed treatment. All patients with scabies attending our clinics are given a simple but detailed typed proforma on treatment, which they are made to read before taking it home with them. Attention to the patient's environment and activity during the treatment period is important. It is unlikely, for example, that an old-age pensioner living on his own will be able to apply lotion "everywhere below the neck."

Here in the tropics, where all Europeans sweat, even at rest, it is impossible to keep an application on the skin for more than a few hours before sweat washes it off. For this reason we frequently admit our patients to air-conditioned rooms during treatment. While this procedure is obviously unnecessary in the United Kingdom, one can visualize that manual workers, miners, blast-furnace operators, athletes, etc., are unlikely to be able to carry out treatment successfully while remaining at work, and unless all aspects of the patient's environment are considered at the consultation treatment is less likely to be effective.—I am, etc.,

T. C. HINDSON.

Dermatology Department,
British Military Hospital,
Singapore.

SIR,—I have read the recent articles and correspondence on the subject of scabies, and it seems that our experience of this problem may be of interest to others.

Our work involves child health in remote villages in central Tanganyika. Scabies is a serious problem, and in some villages almost 100% of children over 6 months old are affected. In some cases the lesions are so extensive and the secondary infection so severe that it is a factor contributing to the very high child mortality in this area.

I have found benzyl benzoate effective in hospital use but quite useless in the village setting. The patients treated in hospital are promptly reinfected on returning home. The result was that after nine months' work in the villages there was no significant change in the incidence of scabies.

About a year ago we stopped using benzyl benzoate and started using monosulfiram soap, advising the patients to allow the soap to dry on the skin. In this way an effective concentration of monosulfiram is built up on the skin and in the clothes and bedding.

The results have been quite remarkable, and scabies has almost disappeared in some villages. The only obstacle to complete eradication seems to be the cost of the soap at 2s. each in a country where a manual worker earns only 6s. a day when he can find work.

I was surprised to see no mention of monosulfiram in the copies of the *B.M.J.* which have reached me so far.—I am, etc.,

R. W. SMITH.

SIR,—Dr. J. O'D. Alexander's two cases (17 June, p. 766), in which he found acari from scrapings but no recognizable burrows, raise the interesting question whether *Sarcoptes scabiei* may sometimes behave atypically. There are of course occasions when the acarus does not produce a burrow—or not a typical one; this is in fact true of the male and of the larva, but obviously in established scabies there are likely to be burrow-producing adult females as well. Another possibility to be considered is whether the acarus is perhaps of animal origin; sarcoptic mange of dogs is transferable to humans as a follicular rash without burrows.

I am not of course suggesting that this must be the explanation of Dr. Alexander's cases—this would be tantamount to asserting that human scabies cannot occur without burrows, and this kind of negative is unprovable. I cannot myself recall seeing a case of human (as opposed to animal) scabies in which no burrow could be found *somewhere in the family*. In particular an examination of the soles and ankles, which are relatively protected from scratching, is often rewarding.

I heartily agree with Dr. Alexander's last paragraph, and would only add the suggestion that in the case of infants the face and scalp should be included in the treatment. Typical burrows may occur on these sites.—I am, etc.,

Winchester. LIONEL J. BACON.

Problems of Antenatal Care in the Tropics

SIR,—Mr. S. Haroon's article on the problems of antenatal care in the tropics (3 June, p. 617) highlights some of the difficulties confronting the Western-trained doctor who works in these regions. Yet, although the basic problem in the tropics appears to be poverty, there is considerably more clinical variation in different regions than his article suggests. Clinical experience in Western Nigeria,[1] for example, would appear to differ greatly from Mr. Haroon's.

However, despite this clinical diversity, I believe that there are some basic generalizations that can be applied to antenatal care and that these should have had more emphasis in his article. All of them require some reorientation of thought in the Western-trained doctor.

(1) The doctor must learn to delegate authority. He should not regularly undertake routine tasks that can be done by others under his supervision. This means in practice that most of the work of an antenatal clinic is done by the nurses and that the nurses themselves may give some routine work—for example weighing and urine testing—to unqualified helpers. The doctor, therefore, is much more an organizer, supervisor, and teacher than he would be in the West.

(2) The doctor will need to turn his thoughts towards preventive medicine. This will bring him to the realization that one of his major functions is teaching. Antenatal mothers provide a captive audience who are particularly receptive to health teaching. If this teaching can be linked with, and continued through, the postnatal and paediatric clinics it provides one of the most successful ways of raising the standard of health in a community. In my opinion health teaching is one of the most important functions of an antenatal clinic and all members of staff from the top to the bottom should take part in it.

(3) The doctor will have to think very carefully about the cost of the care he is providing. If he wishes to help the people among whom he works he must provide care that all can afford, for the provision of an expensive service to an affluent minority does little to help the community at large. This may mean pruning some hallowed antenatal procedures.

(4) The doctor must believe sufficiently in the importance of clinical research to do some himself. The medical needs in a tropical area are often unknown. An efficient obstetric service cannot be created until these needs and their relationship to the local culture have been discovered. For example, in my own area it is more important to estimate the haemoglobin regularly than to weigh the patient, or even to take her blood pressure routinely. Antimalarials are of far greater benefit than iron tablets.

(5) The doctor must stray purposefully outside his specialty. A recent editorial sums this up particularly well.[2] A mother will see little profit in good clinical care in pregnancy and labour if her child soon dies of malnutrition or endemic disease.

In the poor countries of the tropics the family's first contact with modern ideas on health is often through the antenatal clinic. If the mother accepts the teaching she receives there she is likely to apply it to the whole family. This may help to bring under control the enormous loss of life in infancy and early childhood from readily preventable conditions.—I am, etc.,

Treatment of Choriocarcinoma

SIR,—May I reply to the letter on this topic sent to you by Professor W. S. H. Tow and Dr. W. C. Cheng (17 June, p. 764)? Again, as before, my primary concern is with logic and pathology. Thus:

(1) Untreated choriocarcinoma is a metastasizingly malignant lesion, equally lethal in young and old, nullipara and multipara. For its eradication hysterectomy is either believed to be optimum basic treatment or it is not. If it is believed to be so hysterectomy will always, when practicable, be performed; and it necessarily follows from this that if, in these circumstances, hysterectomy be *not* performed either optimum treatment is not being used or the therapist is not translating his belief into practice. To withhold what is believed to be optimum treatment for the eradication of a cancer just because the patient is young or nulliparous seems to me illogical.

(2) It is surely of the essence of medical or any other science that comparison be continually made between thought, method, and result in one centre and another. Professor Tow and Dr. Cheng say that they do not consider such comparison to be fruitful at present, and this I think most strange.

(3) It is a prime necessity for interchange of opinion that agreement on terminology be achieved as far as possible. To be sure, there is still room for debate in the case of lesions of trophoblast, but in using the (by current standards) self-contradictory term "villous choriocarcinoma" Professor Tow and Dr. Cheng stand virtually alone. In the histopathology of neoplasia diagnosis is prognosis; by this tenet "villous choriocarcinoma" as a diagnosis fails.

(4) I cannot have expressed myself clearly enough in criticizing the use of the term "a trophoblast" to designate a cell. Instead, may I ask what kind of cell do Professor Tow and Dr. Cheng consider "a trophoblast" to be?—I am, etc.,

Varicose Veins, Oral Contraceptives, and Thromboembolism

SIR,—Mr. G. Fegan in his letter (24 June, p. 838) comments on our report (3 June, p. 637) of fatal thromboembolism following injection of varicose veins. We are at this clinic comparing the injection/compression technique with a conventional scheme of operative treatment in a trial supported by the Ministry of Health, and therefore followed the method used by Mr. Fegan himself. We would like to take this opportunity to thank him for teaching us at his clinic in Dublin.

The case reported was treated by one of us personally. Only 5 ml. of sodium tetradecyl sulphate was injected. The bandages were undisturbed when embolism occurred the following day.

We apologize again for stating the dose as 10 ml. When this error was discovered we reported it at once to you (17 June, p. 778) and to Mr. Fegan. We agree that personal attention to detail is essential for safe and successful treatment, and that ascending great saphenous thrombophlebitis should not occur. We have seen this complication only twice, each time after the patient has removed the bandages contrary to firm instructions given both verbally and in writing.

We think it may be significant that the opposite leg of this patient had been treated successfully and without complication at a time when she was not receiving hormone therapy.—We are, etc.,

H. O. JONES.

Lyell's Toxic Epidermal Necrolysis

SIR,—We were very interested to read the article on Lyell's disease by Dr. J. Jefferson (24 June, p. 802), particularly as we admitted a similar case on 12 June which caused a great deal of diagnostic difficulty.

This was a 2-week-old female child who had been restless and irritable for two days. On the day of admission the mother had taken her to the local child welfare clinic, where it was noted that she had a blepharitis, and was given sulphacetamide eye ointment to apply. Five hours later the mother noticed the skin was peeling off the child's buttocks and brought her to hospital. The main clinical findings were a temperature of 99° F. (37.5° C.), general erythema of the skin (boiled lobster appearance), patchy areas of moist erythema with yellow crusts on the face, particularly around the mouth, nose, and eyes, and large patches of what appeared to be scalds of the perineum, buttocks, and trunk. In view of the appearance of the child's skin and the state of agitation of the mother (who was 17 years old, and this was her first child) it was suspected that she had been accidentally scalded, but the mother was emphatic that there was no possibility of this. In addition, the child showed no evidence of shock, dehydration, or systemic disturbance. A swab from the facial lesions yielded a heavy growth of *Staphylococcus aureus* resistant to benzylpenicillin.

Treatment was on the same lines as that described by Dr. Jefferson, except that the child was nursed in a gallows splint to keep the perineum exposed. All the skin lesions healed completely within two weeks, and at no time throughout her stay did the child show any evidence of systemic disturbance.—We are, etc.,

W. S. JAMIESON.
I. CAPPERAULD.

Royal Herbert Hospital,
London S.E.18.

SIR,—I was interested to read the article by Dr. J. Jefferson (24 June, p. 802), as in my experience as a consultant physician in Aden in the last two years epidermal necrolysis is not uncommon in European infants there. Although minor degrees of the condition are seen, some 15 infants and young children had lesions extensive enough to need hospital admission.

Staphylococci were isolated from the great majority of the children, although no facilities existed for phage typing. Localized skin sepsis preceded the characteristic "scalded" appearance in some patients, and several had received tetracycline orally or topically before admission. It is not possible entirely to exclude this drug as a sensitizing agent, but it is most unlikely both from the time interval and the fact that it was common to a minority of patients with a similar clinical picture. Progress was generally towards complete skin healing in 10–11 days, and typically the neck and perioral areas were slowest to heal. Our treatment regimen was similar to that of Dr. Jefferson, but I am not convinced that treatment ever significantly shortened the time taken for the skin to heal.

The disease was fatal in one 9-week-old male infant who had 75% skin involvement and required replacement of considerable fluid losses as in a burn of similar extent. Terminally this infant developed digital gangrene, and necropsy showed a necrotizing endarteritis with gangrenous dermatitis and little inflammatory response.

In other particulars our cases resembled others described, and I would emphasize the distress and irritability of the affected infant which is almost certainly due to widespread skin tenderness.

Apart from this picture, staphylococcal skin lesions are commonly bullous in Aden and other parts of the Middle East, and it is tempting to suggest that climatic conditions potentiate the action of a specific staphylococcal lysin, perhaps by increasing skin permeability in a non-immune subject.—I am, etc.,

D. J. STOKER.

Royal Air Force Hospital,
Wolverhampton, Staffs.

Heavy Uterine Bleeding

SIR,—Both your expert (20 May, p. 494) and Mr. J. M. Gate (1 July, p. 47) have given a somewhat misleading reply to the questioner who asked about uterine bleeding and abnormality of the clotting mechanism.

While a non-gynaecological cause for uterine bleeding occurs in less than 1% of cases, because of the frequency of consultations for this symptom considerable numbers of haematological disorders present to the gynaecologist and obstetrician. Many of these are cases of idiopathic thrombocytopenic purpura, and less commonly, as Mr. Gate indicates, other disorders are present such as aplastic anaemia or leukaemia. Thus thrombocytopenia from any cause may be responsible.

In von Willebrand's disease uterine haemorrhage is often far more of a problem than your expert suggests. I have seen catastrophic haemorrhage at menarche, several severe postpartum haemorrhages, and prolonged heavy menstrual bleeding causing severe iron deficiency, not controlled by progestogens, and requiring hysterectomy. Rarely patients with pseudo-xanthoma elasticum and the Ehlers–Danlos syndrome suffer menstrual disturbances, but this has not been a prominent aspect of the cases seen here.

Your expert further states that deficiencies of coagulation factors do not cause uterine haemorrhage; this is usually true for congenital afibrinogenaemia, but patients deficient in factors V, VII, X, and XI sometimes suffer frequent heavy periods and also postpartum haemorrhage.—I am, etc.,

J. J. TAYLOR.

Queen Elizabeth Hospital,
Birmingham 15.

"Swallowed" Endotracheal Tube

SIR,—Following Mr. J. A. S. Dickson and Mr. G. C. Fraser's recent article on "swallowed" endotracheal tubes in neonates (24 June, p. 811), may I report a further similar case transferred to this hospital?

The infant was born by lower segment caesarean section following a trial of labour for disproportion. Birth weight was 8 lb. 11¾ oz. (4 kg.), and the Apgar score was 2. Resuscitation was carried out and included intubation with a Portsmouth tube. The child rapidly improved and remained well until the fifth day, when he began to vomit. Vomiting at first occurred two or three times per day, but became more severe and frequent. Between vomiting the child was retching forcibly. On the tenth day the vomitus contained bile, and he was transferred here. His weight was found to be 8 lb. 3 oz. (3.7 kg.), but there were no abnormal physical signs except the repeated retchings, which occurred approximately every 30 minutes. A test feed was carried out. The child took the feed eagerly, the stomach became moderately dilated, and small peristaltic waves were seen. X-ray revealed a Portsmouth tube, the lower end impinging on the greater curvature of the stomach, the upper end lying in the upper end of the oesophagus. The tube was removed easily under general anaesthetic, using a straight laryngoscope and a pair of tonsil-holding forceps. The child made an uneventful recovery, and vomiting ceased immediately.

In retrospect it was remembered that during resuscitation of the infant the anaesthetist had been recalled to the mother urgently.

The interesting feature of this case was the length of time between "intubation" and the removal of the tube. In all Dickson's cases removal appears to have been carried out soon after birth, when the child's condition had improved. In this case removal was carried out on the tenth day. Despite this the child's general condition had remained good and his weight was only 8¾ oz. (250 g.) below the birth weight. No long-term effects are anticipated.—I am, etc.,

MICHAEL G. PRINN.

Queen Elizabeth Hospital for Children,
London E.2.

Enuresis and Psychiatry

SIR,—I have recently been asked to see an 18-year-old enuretic boy who originally attended a child guidance clinic 10 years ago for that complaint, for which he received psychotherapy for a while, but no attempt was made to deal with the symptom specifically. The family has been in touch with the clinic ever since, during which time the mother must have had to cope with over 3,000 wet beds, yet the clinic thought it best to ignore the problem (easier for them than for the mother to do). Last year the boy's sister, now aged 8, also began psychotherapy there for enuresis, but the indirect approach has again been adopted.

In certain psychiatric circles it is regarded as disastrous to tackle a symptom directly, however unpleasant it may be. The reason usually given is that the symptom is only the visible part of the iceberg, and the greater, more important part lies below the surface; unless this is dealt with other symptoms will replace the one that is removed. As if unable to tolerate any challenge to this kind of dogma, some psychiatrists have been known to warn the parents of enuretics that successful treatment (with the buzzer) may give rise to impotence later in life. On reflection, it is apparent that this form of therapeutic nihilism is unhelpful, to say the least, to the patient, and borders on the unethical. It seems to me:

(1) Substitution symptoms have never been shown to develop in a significant proportion of enuretics successfully treated.

(2) Even if they did develop they might well be less humiliating and upsetting to all concerned.

(3) And there is no reason why the underlying iceberg should not be treated concurrently with the direct attack on the wetting or other symptoms anyway.

Asthma, enuresis, epilepsy, and migraine all have much in common. They are all inherited, usually improve with age, reflect emotional tension, and respond to symptomatic treatment. Now that the latter is so much more effective than it used to be, it seems that to withhold it is to do a disservice to one's patients.—I am, etc.,

IAN G. WICKES.

North Middlesex Hospital,
London N.18.

Ophthalmic Graves's Disease

SIR,—In relation to your leading article "Ophthalmic Graves's Disease" (6 May, p. 329) and Mr. Kenneth C. Wybar's letter (24 June, p. 836), may I point out that Henderson[1] has obtained excellent results (in several cases of lid retraction in Graves's disease) by the procedure of severing the attachment of Mueller's tarsal muscle from the tarsal plate.

This is a significant pointer as to the aetiology of lid retraction in Graves's disease.—I am, etc.,

D. K. RAY.

Blackwood, Mon.

Carbenoxolone Sodium

SIR,—It has been pointed out to us that in our medical memorandum (18 February, p. 412) we have described carbenoxolone sodium (Biogastrone) as the disodium salt of β-glycyrrhetinic acid. This should have read the disodium salt of the hydrogen succinate derivative of β-glycyrrhetinic acid.

Some confusion also appears to have arisen owing to the fact that certain methyl groups and double bonds were omitted from the formulae of β-glycyrrhetinic acid, aldosterone, and cortisone. The formulae as presented were simply to demonstrate a similarity in the basic structure of the three compounds.—We are, etc.,

Victoria Infirmary, Glasgow S.2. — N. MACKAY.

Royal Infirmary, Glasgow. — CHARLES FORBES.

Cervical Smears

SIR,—For over a year I have been carrying out cervical smears on all my female patients between the ages of 25 and 65 years. Now that the Minister of Health has recognized the need for this service,[1] and has agreed to the payment of 7s. 6d. per smear, the lower age limit has been raised to 35 years. I recently carried out smears on two of my patients under the age of 35, and my claims for payment were rejected.

I am wondering on what grounds this age limit has been applied. If the Minister has been informed that women under the age of 35 do not get cervical cancer his information is not in accord with the experience of the pathologist who has kindly read the smears for me, and who tells me that 20% of all his positive smears occur in women under the age of 35. If, on the other hand, the Minister has been told that there is a shortage of readers and pathologists I can only point out that since January 1966 I have taken smears whenever I have considered it necessary, and they have been read without question. (For this help I should like to record my thanks to Dr. C. H. Wrigley, of the Royal Hampshire County Hospital at Winchester.)

I feel that the decision about when a cervical smear should be taken should be left to the patient's personal physician, and not be dictated by someone in Whitehall. I hope that the British Medical Association may be able to persuade the Minister to accept this view.—I am, etc.,

MICHAEL B. CARSON.

Lymington,
Hampshire.

Live Donors for Renal Transplantation

SIR,—In your leading article (11 March, p. 581) on "Dilemma of Irreversible Renal Failure" you refer to the ethical problems of taking a kidney from a healthy person. After consideration of the use of the kidneys taken from cadavers, you say "Close relatives of compatible tissue group might still wish to donate kidneys, since the results would probably be better than those from unrelated donors." With the exception of identical twins, the statistical chance of transplantation succeeding is not overwhelmingly greater in the case of compatible relatives than of cadavers. The use of a 10-year-old boy as a donor for his identical twin has recently been discussed by Murray and by Lynch.[1] We feel that it is only very rarely that the use of a young live donor can be justified, and cite the following personal experience with identical twins in support of this view.

On 3 October 1962, a 23-year-old girl was admitted suffering from terminal renal failure. She was referred to us because her general practitioner had read a leading article in your journal referring to successful kidney transplantation between identical twins.[2] She was very ill on admission, with generalized oedema and a blood pressure of 260/210 mm. Hg. Vision was very poor and she could see faces only as a blur. There was detachment of the lower one-eighth of both retinae, which by the following day had progressed to a funnel-shaped detachment of both retinae, the central area remaining attached though oedematous. The blood urea was 438 mg./100 ml.; plasma sodium 125 mEq/l., potassium 4.6 mEq/l., chloride 79 mEq/l., and alkali reserve 12 mEq/l., haemoglobin 5.2 g./100 ml. The hypertension was energetically treated with Apresoline (hydrallazine) and Vegolysen (hexamethonium bromide), and she had a three-and-a-half-hour dialysis on the twin-coil kidney on the day following admission. After this treatment the blood pressure was 210/130, and the blood urea was 195 mg./100 ml.

The patient's twin was found to resemble her physically, and was willing to act as a donor for her sister. The blood groups of the two girls were identical in the ABO, Rh genotype, MN, S, P, Le^a, Kell, and Fy^a groups.

At this point the parents of the two girls asked whether, if a kidney was successfully transplanted from one girl to the other, the patient's sight would recover. If this was not likely to happen they were reluctant for the transplant to take place. The potential donor herself was willing to give a kidney. Mr. E. C. Cowan kindly saw the patient and expressed the view that if the patient's general condition could be improved there was at least a possibility the retinae might reattach and useful sight return. Accordingly it was decided that the patient should be treated by further dialysis to prepare her for transplantation at a later date. Investigation of the healthy twin was planned, to ensure that she had two normally functioning kidneys, and that the renal vessels were suitable.

Three days after the first dialysis the blood urea had risen to 275 mg./100 ml., and a second dialysis on the twin-coil kidney was commenced. After three hours a rise in blood pressure and pulse rate caused us to discontinue the dialysis. Despite this tachycardia increased to 180 per minute, and one hour later she had a convulsion, during which she died.

On 27 January 1967, the healthy twin was referred to one of us complaining of urinary incontinence. She had been delivered of a healthy infant by caesarean section on 3 September 1966, after a 34-hour labour. Within a short time following she became incontinent and used a sanitary pad every hour. She had never previously had any urinary symptoms.

On examination she was perfectly normal in every respect except that there was a continual leakage of urine from the vagina. Apart from the presence of occasional pus cells, her urethral urine was free from protein, and sterile on culture. The blood urea was 31 mg./100 ml. Intravenous pyelography showed marked hydronephrosis of the left kidney. There appeared to be an irregular filling defect in the left upper aspect of the bladder outline. Apart from being a little low in position, the right kidney was radiologically normal. On 9 February vaginal examination showed that urine high in the vault appeared to be coming from the cervical os. Cystoscopy revealed a normal bladder with two normally placed ureteric orifices: a catheter could not be induced to pass up more than 2 cm. into the left ureter. Injection of dye produced no useful information. Abdominal exploration revealed that the left ureter, 1 cm. in diameter, was involved in a fibrotic process as it passed the cervix. The fistula was clearly seen entering the cervical canal and the distal ureter was normal.

The damaged ureteric segment was excised and continuity was re-established, leaving a T-tube above the anastomotic site through a proximal uterostomy. Subsequently, a second laparotomy was carried out because dye could not be coaxed downwards into the bladder. The distal limb of the T-tube was blocked by sticky debris. A number 10 ureteric bougie passed easily from the ureterostomy across the anastomosis to the bladder.

Unfortunately, about 10 days later she developed ileus with peritoneal signs. At a third operation urine was found to have extravasated intraperitoneally from the ureterostomy site despite external drainage. The opportunity was taken again at this time to confirm the adequate patency of the distal repaired ureteric segment. By adequate extraperitonealization of the ureterostomy site with external drainage the patient's wound was completely dry over the next 10 days.

The further convalescence was complicated by a coliform infection of the urine. The organism was resistant to sulphonamides, ampicillin, nitrofurantoin, and tetracycline, but was sensitive to nalidixic acid. Despite the in-vitro resistance to nitrofurantoin, the infection cleared following treatment with this for two weeks, and at review one month later the urine was free from protein, cells, and organisms. During the period when urine collected within the pelvis the blood urea rose to 61 mg./100 ml., but subsequently fell to well within normal limits.

If this patient had given a kidney to her twin sister there is every likelihood that it would have been the left one which would have been used. It could therefore be argued that if she had been used as a donor she would have been spared the lengthy illness described above, as there would have been no left kidney to form a fistula into the cervix. However, what if the ureter to be damaged by the caesarean section had been a right and only ureter because the left one had previously been removed? There is also the fact that this patient had a urinary infection with hospital type of coliform organisms resistant to several antibiotics commonly used in the treatment of urinary infections, and this may recrudesce to give further trouble. Late stenotic complications following ureteric anastomosis are not unknown. We feel thankful that this patient had not been used as a kidney donor, although at the time that this was considered we did not think that there was any ethical objection to the use of an identical twin as a kidney donor.

In view of this experience and the fact that it has been reported many times that glomerulonephritis can recur in a transplanted kidney we would now have reservations to the use of any young person, even if an identical twin, as a donor.—We are, etc.,

Radioactive Corpses

SIR,—With reference to your leading article on Radioactive Corpses (6 May, p. 331) the method in use at this institute for warning the mortuary attendant that a body is radioactive is as follows.

For all large radioisotope therapy doses the patient is admitted for an appropriate time dependent on the nature of the isotope, and its biological half-life, and a note is sent to the pathologist to the effect that "If patient X presents for necropsy before a certain date he is to be regarded as a radioactive hazard and the physicist called." This note is pinned behind the mortuary door and discarded after the given date. The responsibility for the issue of this note lies with the senior staff of the radioisotope unit.—I am, etc.,

Cancer Institute,
Melbourne, Australia.

Health of Students and Soldiers

SIR,—I read your leading article "Health of University Students" (20 May, p. 457) with considerable interest, and would heartily endorse the policy advocated regarding the state of rapprochement required in the staff/student complex.

I must, however, take issue—if I have interpreted the wording aright—with the suggestion that the control of health in the armed Forces carries a lesser personal touch than that in universities. Certainly, so far as the Army is concerned, and I believe that similar principles apply in the other Services, great emphasis is laid on this very aspect of man-management. If control is to be exercised in any context, then responsibility must be defined. In the Army, responsibility for health devolves on its commanders (in the broadest sense), advised or assisted by the medical services.

While it would obviously be unrealistic to expect a divisional commander and his assistant director of medical services to be *au fait* with the health problems of every man in the division, it is a very different story when one comes down to regimental or battalion level. By tradition, and in practice, this is a close-knit, almost a family community. It would be absolutely wrong to judge that the "usual channels," as might be implied by the less well-informed reader of your leading article, inevitably lead to an impersonal approach to matters of health.

The regimental officer is fitted by training and by situation to be qualified, perhaps uniquely so, to observe, to advise, and generally to care for the men under his command. And associated with the regimental officer in the field of health, and in their common goal of conservation of highly and expensively trained military manpower, is the regimental medical officer. He is the man who must fulfil many roles, both advisory and executive. He does not necessarily wait to be asked for advice, although he must be freely available for consultation. It is his duty to identify himself with his unit, to know its role, to acquire a knowledge of the tasks undertaken by its members, and to help seek out weak or potentially weak links in the health chain, whether these are personal or environmental.

It might indeed be postulated that any university planning a health service could do very much worse than to base this on the practice of the nearest regular battalion of one of our county regiments.—I am, etc.,

Smoking and Atherosclerosis

SIR,—In a previous letter on this subject (16 April 1966, p. 984) I suggested that smoking and dietary sugar affect the arteries in a similar way. Further work with the help of heavy-smoker volunteers indicates that the atherogenic effect of smoking might lie in its ability to induce hyperinsulinism. This conclusion is based on the following experiment.

Twelve male and seven female volunteers were chosen with the only criterion in their selection that they habitually smoked 20 cigarettes, or more, per day. Their ages ranged from 25 to 57 years. After explaining the purpose of the trial, the subjects were asked to fast overnight and abstain from smoking until a fasting blood sample was taken. Each subject then smoked two cigarettes in succession while talking to each other or reading magazines. A second specimen of blood was then withdrawn. After this, each subject was given 100 g. glucose in water, and further specimens of blood were collected at set intervals for blood glucose and serum insulin estimations. According to the original plan, subjects volunteered to abstain from smoking for 14 days after the first part of the experiment, but only three males and two females were able to do so. The above test was then repeated on these subjects. Glucose levels were estimated by the method of Folin and Wu, and serum insulin by immunoassay.

In the accompanying Table are shown the blood glucose and serum insulin levels in the fasting state, before and after smoking two cigarettes, and during the glucose tolerance test. The values found during the period of heavy smoking and after the cessation of smoking for 14 days may also be compared.

Comparison of Blood Glucose and Serum Insulin Levels

Subject and Sex	Stage of Trial	Glucose (mg./100 ml. Blood)					Insulin (μu./ml. Serum)				
		Fasting		30 min.	60 min.	120 min.	Fasting		30 min.	60 min.	120 min.
		Before Smoking	After 2 Cigarettes				Before Smoking	After 2 Cigarettes			
1 M	30 cigarettes/day ..	92	100	151	112	90	87	96	150	156	102
	Stopped 14 days ..	73	78	136	105	70	29	32	54	67	47
2 M	30–40 cigarettes/day	85	90	127	103	84	52	58	112	100	61
	Stopped 14 days ..	66	83	112	100	80	35	40	63	57	38
3 F	25–30 cigarettes/day	98	95	134	119	88	99	96	145	158	98
	Stopped 14 days ..	54	81	126	102	80	86	88	112	110	91
4 F	20–30 cigarettes/day	90	98	145	120	87	33	30	95	84	40
	Stopped 14 days ..	73	108	141	118	80	8	11	26	22	13
5 M	50 cigarettes/day ..	78	84	135	100	89	53	50	149	124	80
	Stopped 14 days ..	69	87	137	99	90	30	34	86	72	66

If excessive insulin response can be defined as insulin levels rising above 100 microunits per ml. serum during an oral glucose tolerance test[1] then subject No. 4 may not be considered to have hyperinsulinaemia. However, the marked drop in insulin response after she stopped smoking for 14 days indicates a relative hyperinsulinism during the period of heavy smoking. The view that hyperinsulinaemia is atherogenic is well documented.[2–5] The suggestion that it is the factor responsible for the liability of heavy smokers to develop atherosclerosis is an expansion of this theory.—I am, etc.,

"Escape from Sanity"

SIR,—On the night of Friday, 9 June, I viewed a television programme entitled "Escape from Sanity" from beginning to end.

As nearly everyone will know, the subject dealt with was schizophrenia, and I regret to say that I consider the presentation to have been an appalling exercise in bad taste. In my opinion it also sailed very near the wind ethically, for I remain to be convinced that all the patients shown were in a condition to give free and comprehending consent to taking part.

As a medical officer of health I am concerned with health education, but the public exhibition of personal suffering and anguish has no place in my concept of this subject. The programme as shown appeared to me to be of very little practical value as an educational project directed towards the lay public, and should never have been mounted on a medium where it is impossible to divorce education from entertainment.

One of the less pleasing features was towards the end, when an apparent member of our profession made a public confession of almost complete ignorance of the subject, which was surely quite unnecessary, and can hardly have done much to improve our image in the eye of the man in the street, or to increase his faith and confidence in us.

Lest any of our more "progressive" colleagues, or members of the staff of the B.B.C., may think that this was an enlightened venture I would remind them that in the eighteenth century lunatic asylums (Bedlam) were opened to the populace for their entertainment by our barbarous and reactionary forebears. Now in the second half of the twentieth century we put patients suffering from mental disorders on television for the edification of the citizens of the Welfare State—such is progress.—I am, etc.,

Research in General Practice

SIR,—It is becoming increasingly clear that one of the most fruitful remaining fields in which the general practitioner can contribute to the advancement of medicine is in epidemiology. This is particularly true in relation to the regular outbreaks of well-circumscribed "influenzal-like" illnesses which afflict every practice throughout the year. Some of these illnesses, though self-limiting, produce a surprising degree of debility, especially among young adults, and with the advent of specific anti-viral agents perhaps in the foreseeable future it would seem important for us to begin to map out recognizable clinical patterns and relate them to specific viruses.

In this connexion I have been prompted to report one such outbreak in my own practice. The clinical picture was quite distinct. Typically, the patient was a young adult between 25 and 35 years of age who complained of a severe headache of sudden onset accompanied by a characteristic sharp pain in the ocular muscles made worse by any eye movements. There was photophobia, nausea and anorexia, and slight neck stiffness in most cases. The illness generally lasted about 48 hours, but a few patients were ill for periods of up to two weeks, and these had gross muscular weakness and a curious relapsing pattern to the illness. The temperature was elevated in the severe cases, but many remained afebrile throughout. In most cases where there were children in the house they were either unaffected or had only very mild symptoms.

Owing to the enthusiastic co-operation of the local public health laboratory I was able to have stool cultures tested for viruses from most of the cases, and they succeeded in isolating E.C.H.O. virus type 9 from 11 out of 16 cases.

Perhaps the most enlightening feature of this piece of elementary research was the ease with which it could be carried out during routine visiting even when under fairly heavy pressure of work. The patients were uniformly delighted that something positive was being done apart from soothing words and aspirin, and were happy to collect, label, and post their own specimens. Complicated apparatus and time-consuming procedures are simply not required for this sort of study, which I feel might, if sufficiently intensified, produce something of real value.—I am, etc.,

L. P. MARTIN.

Coroners' Jurisdiction

SIR,—Your correspondent Mr. H. A. Kidd (3 June, p. 642) seems to have lost sight of the true function of the coroner in his suggested reforms, and to have ignored the fact that the interests of the medical profession are not the only consideration which should guide the Crown and its officers in the discharge of their obligations to the community.

The fact that there has been criticism of the coroners' jurisdiction "not only by doctors but also by members of the legal profession" does not prove anything, more especially when one remembers that it is a minority of each profession which is involved, that in each case the grounds of criticism differ, and that the remedies suggested by each profession are quite different and only suited to their own particular purposes.

The Crown has a constitutional obligation to protect life, and in discharging that obligation it relies upon coroners to investigate publicly all deaths due to unnatural causes. As a preliminary to this, the coroner must be informed of all deaths which are not known to be natural, so that he can decide upon which he must hold inquests, and as a result of it he must ensure that steps are taken "to prevent the recurrence of fatalities similar to that in respect of which the inquest is being held."[1]

The premises, therefore, upon which the jurisdiction is based are quite simple, and, I would suggest, unassailable from the point of view of the public interest. Difficulties mainly arise out of the fact that, whereas elaborate rules of procedure have been laid down for the guidance of coroners, no official attempt has yet been made to define what are "unnatural causes."

At present each coroner uses his own criteria in considering this fundamental matter, and I would suggest that herein lies the main point of confusion as far as the medical profession is concerned. If Mr. Kidd is interested in this subject it is discussed in some detail in an article to which I have contributed.[2]

In making his arrangements a coroner should consider: firstly, his duty to the Crown; secondly, the convenience of bereaved relatives; thirdly, his other essential commitments; fourthly, the convenience of witnesses, among whom doctors form an important minority; and, finally, his own personal convenience. It is inevitable, therefore, that not everyone can be satisfied.

The suggestion that a coroner should meet or discuss with medical staff before deciding whether to hold an inquest is vague. If the meaning is that a coroner should be thoroughly acquainted with all the circumstances of a case, and in particular with the medical aspects of deaths arising in hospital—for example, prognosis with or without treatment, inherent risk of treatment etc.—then I would readily accept it. If, however, Mr. Kidd expects the coroner to be influenced by the views of a surgeon on the desirability of holding an inquest then he must surely consult also the drivers of cars and the owners of factories, who in other cases are equally liable to embarrassment. This would be a complete abdication of his responsibilities.

No system is perfect, and isolated occasions will always arise in which doctors by folly or by lack of sophistication fail to do justice to themselves in the witness-box, but the publicity is soon forgotten provided that they themselves do not draw attention to it or prolong it. This is surely one of the hazards of medical practice and is more than compensated by the esteem in which those are held who adhere to their ethical and professional standards. Those who appear to have neglected these standards only make news because the vast majority of their colleagues maintain them, and in so doing have nothing to fear from appearing at an inquest.—I am, etc.,

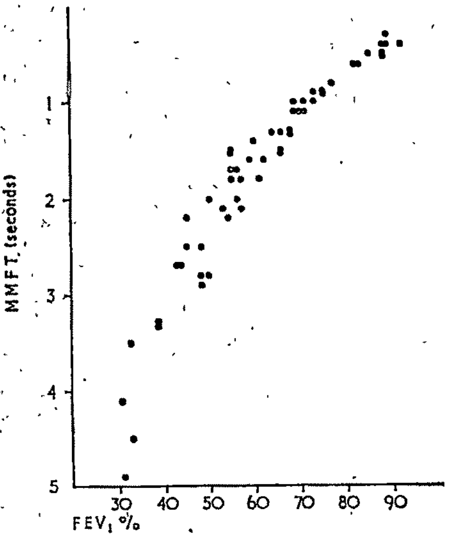
Maximal Midexpiratory Flow Time

SIR,—The first-second forced expiratory volume (F.E.V.$_1$) expressed as a percentage of the forced vital capacity (F.E.V.$_1$%) or unforced vital capacity (F.E.V.$_1$/V.C.%) is widely used as a test for airflow obstruction. The maximal midexpiratory flow rate (M.M.F.R.) and maximal midexpiratory flow time (M.M.F.T.) were introduced by Leuallen and Fowler[1] as tests of ventilatory capacity that were particularly sensitive to obstruction; attention has hitherto been given mainly to the M.M.F.R. We have recently studied the M.M.F.R. and M.M.F.T. in relation to the F.E.V.$_1$ and F.E.V.$_1$%. The measurements were carried out on 54 subjects (46 patients with chest diseases and 8 normal subjects) using a dry recording spirometer (Vitalograph). The M.M.F.T. was found to correlate closely with the F.E.V.$_1$% ($r = -0.94$), except in very severe obstruction, when an M.M.F.T. longer than 3.5 seconds was not matched by reduction in F.E.V.$_1$% below about 30 (see Figure). The

M.M.F.R. did not correlate well with the F.E.V.$_1$%.

We believe there are a number of advantages in including the M.M.F.T. in clinical spirometry:

(1) It can be read quickly from the spirogram, and the presence and severity of airflow obstruction are immediately apparent from its duration.



(2) It may be a more accurate index of obstruction than the F.E.V.$_1$% in severe cases (M.M.F.T. greater than about 3 seconds).

(3) There is no need to use either the F.E.V.$_1$% or the F.E.V.$_1$/V.C.% in the assessment of those cases in which the two percentages differ markedly.

(4) A discrepancy between the M.M.F.T. and the F.E.V.$_1$% can bring to light a faulty forced expiration, particularly when an inaccurate F.E.V.$_1$% is due to a slow start or an incomplete F.V.C. (the M.M.F.T. being less affected).

The forced expiratory time (F.E.T.), which can be estimated spirometrically and clinically, also correlates well with the F.E.V.$_1$%.[2, 3] However, the spirometric F.E.T. cannot be recorded in patients with moderate or severe airflow obstruction with a spirometer such as the Vitalograph, which runs for six seconds only. Moreover, the F.E.T. may be an exhausting procedure for some patients with severe obstruction; or, if they are not required to complete the expiration fully, it is underestimated. Such incomplete expiration does not affect the M.M.F.T. and F.E.V.$_1$% when the negligible volume of airflow is reached towards the end of the expiration.

In the same 54 subjects we found that the M.M.F.R. correlates moderately well with the F.E.V.$_1$,[4] but that the M.M.F.T. does not do so. Our investigation is continuing and we hope to report on it fully in due course.—We are, etc.,

Fees for Health Certificates

SIR,—It is constantly happening that firms instruct actual or prospective employees to seek medical examinations and certificates concerning fitness for special tasks. Here are quite recent extracts from letters:

(1) From a firm of architects to the general practitioner: "Would you be good enough to supply a certificate stating that Mr. X is in good health and able to undertake a tour of duty in the tropics."

(2) From a large nationalized public utility concern to a youth accepted as apprentice: "Will you please arrange to obtain from your National Health Doctor a certificate as to the general state of your health and your ability to undertake the training we propose to give."

The architects were paying for their employee to fly to and travel in West Africa. The nationalized company's representative told us that the training would cost them £2,000. In both cases they refused to consider the extra of the doctor's fee, which they expected the employee to meet. We believe that fees for such medical services should be the responsibility of the firm which has made the demand. Also that a general practitioner should refuse to examine and to certify unless he has obtained the firm's written agreement to pay.

We should be grateful if this letter were published so that the views of our colleagues could be invited.—We are, etc.,

Appointment Systems in General Practice

SIR,—Dr. J. S. K. Stevenson's paper (24 June, p. 827), as excellent and as informative as his previous ones, provides answers to questions about how patients use his appointments system. They ring true and are probably valid for most practices, with one notable exception: the number of patients who are prepared to wait for a day or two to see a particular doctor. He found it less than 2%. In our group practice, larger than his and with a higher proportion of patients in social class two, it is much higher. In April I took three days' holiday and missed four surgeries on Thursday, Friday, and Saturday. To test the hypothesis that any partner can miss occasional surgeries without overburdening the others, I asked the receptionists to count the number of patients wanting an appointment with me who were not prepared to wait until Monday, when I would if necessary see all who had. Only one patient made an appointment with my partners. It is difficult to express this as a percentage, because we do not know how many would have made appointments had I been there, but the average for the Thursday, Friday, and Saturday of the three subsequent weeks was 70, the lowest being 54. If we assume that 54 would have made appointments in the week in question the proportion of those who would wait at least two and at most four days was 98%.

That patients will wait for their own doctor is so much accepted by us that if one decides to miss a surgery he need not notify the others, because he knows their work will be infinitesimally affected. At the end of an average-sized surgery last Wednesday the receptionist told me there was a casual—that is, someone who had not made a prior appointment. I said that he was not my patient but Dr. X's, and her reply that he was at Durham Regatta was my first intimation that he had not been steadily consulting in the next room for the past two hours.

I suspect that the explanation lies in different attitudes to family doctoring. Dr. Stevenson and his partners do not attach importance to the doctor–patient relationship; we do. Not, as he suggests, because we are egotistical or think ourselves infallible but because it is more efficient. If you know a patient—his medical history, personality, family relationships, attitude to his occupation, reaction to stress, pain threshold—it is easier to get the history of his complaint, it takes less time to make a diagnosis and prescribe treatment, and it is simpler to explain the prognosis in words appropriate to his temperament and intelligence than if he is a stranger. An established doctor–patient relationship is more efficient. That, and not the incidental satisfaction it may give the doctor, is the justification for personal doctoring.—I am, etc.,

ANDREW SMITH.

Newcastle upon Tyne.

SIR,—I read with considerable interest the article by Dr. J. S. K. Stevenson (24 June, p. 827) describing the experiences of a practice of four partners working by appointment only.

My experience in a single-handed practice working by appointment for over three years is so similar as to be worth recording.[1] Of the appointments 98% are made by telephone. The number of patients attending without an appointment fell rapidly to 9% in 1965, 3½% in 1966, and less than this so far this year. The consultation rate has varied very little, but the fall in visiting is quite dramatic. After the introduction of the appointment system the visits in the first two quarters of 1965 were 841, of 1966 714, and of 1967 560. During this period the list has risen by 225 to 2,400.

Among the reasons for this fall in visiting is a much greater preparedness by mothers to bring fractious babies, knowing that waiting-time will not exceed 11 minutes, and that the waiting-room will be almost empty.

We have in fact heard this so often that we are prepared to put some little pressure on patients to bring children when visits are requested. "Are you not able to bring him up?" is a remark often overheard from the receptionist's desk.

The outstanding advantage to me has been our ability to spread the work load to a much greater extent to suit myself and fit my other commitments. All but a small handful of patients have welcomed the system.—I am, etc.,

C. TAYLOR.

Liverpool.

Obituary Notices

Sir ALEXANDER MACGREGOR, K.B.E., LL.D., M.D., F.R.C.P.GLASG., D.P.H.

Sir Alexander Macgregor, a former medical officer of health for Glasgow, and chairman of the Western Regional Hospital Board (Scotland), died suddenly in a Glasgow hospital on 29 June. He was 86.

[Universal Pictorial

Alexander Stuart Murray Macgregor was born in Arbroath on 7 April 1881, and was educated at Hutchesons' Grammar School, Glasgow, and Glasgow University, graduating M.B., Ch.B. in 1904. He spent four years of resident service in the Royal Infirmary and Belvidere Hospital, gaining the M.D. with honours and gold medal in 1908. A year later he took the Cambridge D.P.H. Thereafter he was formally appointed to the staff of the Public Health Department of the City of Glasgow, already notable for the work of two outstanding medical officers of health, to the second of which he was in due time to become the successor. As a major in the R.A.M.C.(T.A.) he served in the first world war, principally at Gallipoli, and in Egypt, Palestine, and Syria ; and the public health problems, military and civilian alike, which confronted him in these theatres of war so stimulated his interest, ingenuity, and enterprise that he was confirmed in his conviction that the field in which he might best exercise his energy was that of preventive medicine. He was mentioned in dispatches four times, and in 1919 was appointed O.B.E. in recognition of his work in combating malaria in Palestine during the war.

After demobilization he returned to Glasgow, and—first as a senior medical officer, and later as deputy medical officer of health—became deeply immersed in the thronging and complex public health problems of a great community faced with the urgent need for enlightenment, advance, and change. He was particularly preoccupied with such things as general sanitation, sewage disposal, slum dwellings, the activities of port medical officer, the provision of adequate hospital facilities for infectious diseases, tuberculosis and the like, and, perhaps above all, with the challenge of infant mortality and the establishment of sound and progressively efficient maternity services. The last was to remain a principal ingredient of his thought until the end of his life.

A member of the British Medical Association, he was honorary secretary of the section on naval and military medicine at the Annual Meeting in 1920, honorary secretary of the tuberculosis section in 1922, and president of the section of preventive medicine in 1930. In 1926 he was elected Fellow of the Royal College (then Faculty) of Physicians and Surgeons of Glasgow.

In 1925 he succeeded Dr. A. K. Chalmers as medical officer of health, a post which he held until his retirement in 1946. The intervening years were spent in unremitting toil, which tended to occupy him into the hours of darkness, and in the inculcation of the basic principles of his profession into the minds of his subordinates. Practice rather than precept was a telling feature of his habit in this regard. Under his guidance, in which details as well as policy governed his actions, all the services for which he was responsible were so shaped as to become models of their kind. This fact was recognized when, in 1941–2, he was elected president of the Society of Medical Officers of Health, an event which coincided with the conferment of the honorary degree of LL.D. by Glasgow University in 1940, and of a knighthood in the following year. He was an honorary physician to the King in Scotland from 1937 to 1940.

The transference to the custody of the Public Health Department of four large general hospitals—Stobhill, Merryflats, Duke Street, and Oakbank—previously administered by the old Parish Council, gave Sir Alexander an opportunity to begin the transformation of what had been indifferent institutions into what have now become the first-line hospitals of Stobhill, the Southern General, the Eastern District, and the Western District respectively. The experience thus gained proved to be of great moment when, in 1947, Sir Alexander emerged from his retirement on being called upon by the Secretary of State for Scotland to assume the chairmanship of the Western Regional Hospital Board, over which he presided for some seven years. For this work he was honoured in 1955 by the appointment of K.B.E. He maintained a keen interest in public health, and in the organization of the health services, to the end of his life, and his book *Public Health in Glasgow, 1905–1946,* appeared only a few weeks before his death.

There are many who in a personal way will remember Sir Alexander as essentially a fertilizer of the mind of youth, and as one who sought consistently to maintain and enhance the dignity of the medical profession. He was a great humanitarian, and his interest in and enthusiasm for the National Health Service was particularly centred in the possibilities which it presented for providing for clamant human needs.

He married in 1910 Miss Margaret Whyte, who died in 1965. He is survived by two sons and two daughters, all of whom are members of the medical profession.—A. K. B.

Sir ARTHUR MACNALTY writes: Sir Alexander was not only appreciated in Glasgow ; he was rightly regarded universally as one of the most progressive and enlightened of public health administrators. His counsel and advice were valued by us at the Ministry of Health and by other health authorities. In the present century great contributions have been made to the progress of public health by eminent medical officers of health like Shirley Murphy, J. C. Thresh, of Essex, John Robertson, of Birmingham, J. Niven, of Manchester, Arthur Newsholme, at Brighton, and William Savage, of Somerset. Macgregor was of this illustrious company. Sir Alexander's chief recreation was golf. He had a kindly and friendly disposition, and was liked by his acquaintances and beloved by his friends. When he was constructing the municipal hospitals of Glasgow he offered me the medical superintendency of one of them. I was inclined to accept, but my chiefs at the Ministry dissuaded me. Sir Alexander has passed on, full of years and honours, with the satisfaction of a life well spent for the betterment of mankind.

Professor FERGUSON ANDERSON writes: With the death of Sir Alexander Macgregor the last of a generation of great Glasgow doctors, famous not only in their own city but throughout the world, comes to an end. He will be remembered for his pioneering work in the Public Health Department in Glasgow, where his advanced and brilliant policy resulted in the development of a first-rate hospital and outdoor clinic service for the city. His broad interpretation of the various relevant Acts of Parliament, and his wide experience of administration, gave Glasgow a range of medical and surgical facilities second to none throughout the land in the corporation hospitals of that time. His lifetime of work in public health enabled him to portray in a most interesting way the conquest of disease in recent years in his book *Public Health in Glasgow 1905–1946.* This clear and vivid account of change and progress in the city has been widely acclaimed. Innumerable consultants in the west of Scotland owed their start in their specialist career to his foresight and his ability to choose his medical staff wisely. His inspired vision of a link between the corporation hospitals and the university came to be, and made possible the great advances in teaching and research which were to come under professors like the late Noah Morris.

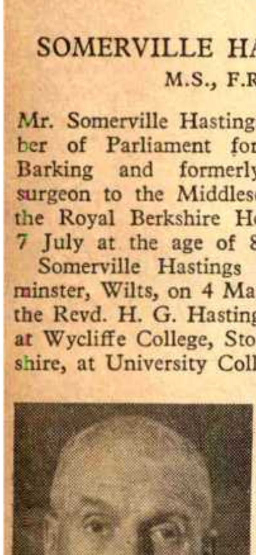
Always of a happy and pleasant disposition, Sir Alexander had a wonderfully cheerful and refreshing faith in human nature which made him a delightful companion. His unique characteristic of charming the opposition into accepting as their concept his own ideas endeared him to those watching with admiration. Although gifted with insight into the frailties of the citizens, especially of his own city, he was unable by nature to speak ill of any man, and he had only friends. Privileged as few are with the possession of a most active mind, he had a retentive memory and outstanding intelligence, and inevitably his advice was sought by great numbers of people from all walks of life.

Sir Alexander married in 1910 Miss Margaret Whyte, who died in 1965, and together this remarkable man and his charming wife enjoyed a long-enduring bond of happiness. The frank and pawky humour of this dear lady made the day-to-day episodes of a busy life an occasion for much laughter and deep understanding between them. Both delighted in being Scots, and the friendly atmosphere of their home allowed no place for humbug or pomposity. Blessed with an alert manner, an upright carriage, and a handsome appearance, Sir Alexander never grew old. In his mature years he would still attract glances from those who saw him as an upstanding and charming gentleman. Throughout his life despite the well-deserved honours he received he remained the most modest of men, anxious wherever possible to remain in the background and with his quiet smile play the part of the interested spectator. Glasgow will not see his like again, and there will be many sad hearts in that great city which has lost a noble servant and an illustrious citizen.

SOMERVILLE HASTINGS, M.B.
M.S., F.R.C.S.

Mr. Somerville Hastings, successively member of Parliament for Reading and for Barking and formerly consultant aural surgeon to the Middlesex Hospital, died in the Royal Berkshire Hospital, Reading, on 7 July at the age of 89.

Somerville Hastings was born at Warminster, Wilts, on 4 March 1878, the son of the Revd. H. G. Hastings, and was educated at Wycliffe College, Stonehouse, Gloucestershire, at University College, London, and at the Middlesex Hospital. While at University College he won the gold and silver medals in botany, a subject which became a life interest, and he was an entrance scholar and governor's prizeman at the Middlesex Hospital. He qualified M.R.C.S., L.R.C.P. in 1902, taking the London M.B. in the same year and the B.S. in 1903. He obtained the F.R.C.S. in 1904 and proceeded M.S. in 1908. At the Middlesex Hospital he was demonstrator of physiology, a cancer research scholar, and house-surgeon, casualty surgical officer, and surgical registrar. He also held the posts of assistant surgeon at the East London Hospital for Children and at the London Throat Hospital. For many years he was surgeon to the ear, nose, and throat department at the Middlesex Hospital, ultimately becoming consultant aural surgeon and lecturer in his old department. He was associated with the hospital for well over sixty years. Hastings served as a captain in the R.A.M.C. during the first world war and in the Emergency Medical Service in the second world war.



[" Illustrated "

Hastings retired from practice in 1945. In that year he was again returned to Parliament as the first member for the Barking constituency, having previously represented Reading in the House of Commons in 1923–4 and 1929–31. He retained the Barking seat at the general elections of 1950, 1951, and 1955. He did not stand for re-election at the 1959 General Election. In 1960 the freedom of Barking was conferred on him. His election in 1923 made him the first Labour member for Reading, and in the first Labour Government of 1924 he was Parliamentary private secretary to the Board of Education. A member of the London County Council from 1932 to 1946, he became chairman of the hospitals and medical services committee of the council in 1934, and occupied the chair for ten years until he became chairman of the council itself in 1944. In the following year he was elected an alderman. He was the second medically qualified occupant of the chair, the other being Sir William Collins, who was present in 1944 to see Hastings take office.

Hastings assisted in the formation of the Socialist Medical Association in 1929, and in that year joined with other medical M.P.s in promoting the idea of a national health service. Elected first president of the S.M.A. he held that office until 1951. He was also a member of the public health advisory committee of the Labour Party. Always interested in the needs and care of children, he was a member of the Curtis committee and vice-chairman of the children's committee of the L.C.C. He was a member of the Medical Planning Commission which presented its draft interim report in 1942.

He had been chairman of the boards of governors of the Hammersmith, West London, and St. Mark's Hospitals and of the North-east Metropolitan Regional Hospital Board, and a member of the Standing Medical Advisory Committee and of the board of governors of Middlesex Hospital. When the British Medical Association held its Annual Meeting at Portsmouth in 1923 he served as a vice-president of the section of laryngology, and he was president of the section of otology of the Royal Society of Medicine in 1928–9.

In addition to surgical papers in his specialty Hastings published *Summer Flowers of the High Alps, Wild Flowers at Home, Toadstools at Home, Alpine Plants at Home,* and *First Aid for the Trenches.*

Hastings married Bessie, fourth daughter of the late W. C. Tuke. They had one son and one daughter. Mrs. Hastings died in 1958.

LADY SUMMERSKILL writes: The idea of a National Health Service germinated in the hospitable atmosphere of Somerville Hastings's Devonshire Street home. It was there that Somerville with his selfless dedication gathered around him a few socialist doctors who felt that medical advice and treatment should be freely available to all. It was known that thousands of people failed to seek treatment because they could not afford to pay fees. At that time we did not approach the future with great confidence, but our meetings were exhilarating. Somerville was a shy man without personal ambition, and he was greatly revered by his colleagues in the Labour Party. He was the complete tolerant Christian. Although a teetotaller, he felt it his duty as a host to provide the type of refreshment which some of his less enlightened friends desired. He was a doctor who was not content with exercising his particular skill upon his patient, but was broad enough in outlook to realize that his whole environment had to be considered. His professional life was restricted to the narrow confines of the ear, nose, and throat, but he sought to impress upon the public the relationship between good health and satisfactory social conditions. Nearly 40 years ago he organized a team of doctors to make a survey of the living conditions of some of the poorer people in Hammersmith, and this showed that poverty and bad housing resulted in physical and mental inferiority. It is pleasant to think that much of what this exceptional man fought for has been achieved, at least in this country.

Lieutenant-Colonel W. C. GRAY, M.B.
CH.B., F.R.C.S.ED., M.R.C.P.GLASG.
I.M.S.(RET.)

Lieutenant-Colonel W. C. Gray, late of the Indian Medical Service, died in Jersey on 2 June 1967. He was 88.

William Cowan Gray was born on 4 October 1878, and received his medical education at the University of Aberdeen, graduating M.B., Ch.B. in 1901. After holding several resident posts he entered the Indian Medical Service in 1905, and served most of his time in the Madras presidency. He held several of the larger and more onerous of the civil surgeoncies in South India, and on two occasions filled a leave vacancy as professor of obstetrics at Madras Medical College and superintendent of the women and children's hospital in that city, where his competence and kindly disposition are still remembered. During periods of study leave he became F.R.C.S.Ed. and F.R.F.P.S.Glasg. On the reorganization of the faculty he became M.R.C.P.Glasg. He had lived in retirement in Jersey for many years.

Sir CLAUDE FRANKAU, C.B.E.
D.S.O., M.B., F.R.C.S.

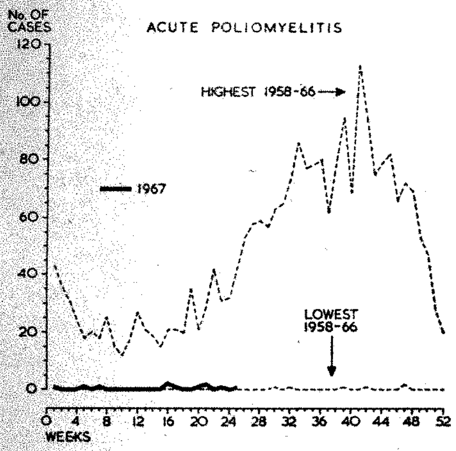
Mr. H. F. ANDERSON writes: Claude Frankau (obituary, 8 July, p. 116) was one of the great general surgeons. He was a towering personality, both surgically and physically. As students we all wanted to be on Claude's firm, and when we qualified we all wanted to be his house-surgeon. The lucky ones became his registrar. He was a superb and courageous surgeon, undertaking anything that was asked of him provided he believed that surgical intervention offered his patients relief from their symptoms. He was also the "doctor's doctor," for it was to Claude Frankau that his colleagues turned when in search of surgical help. He was the most sought-after teacher of his time. His teaching rounds on Tuesday afternoons, always starting punctually at half past one, were open not only to his firm but to anyone in the hospital. His rounds were attended by a large following comprising surgical dressers, more senior students, and housemen and registrars who were working for higher examinations. Secondly, his teaching was simple and direct and above all clinical. His passing will be mourned by generations of students at St. George's Hospital who had the privilege of benefiting from the humanity of his surgery and the greatness of his teaching.

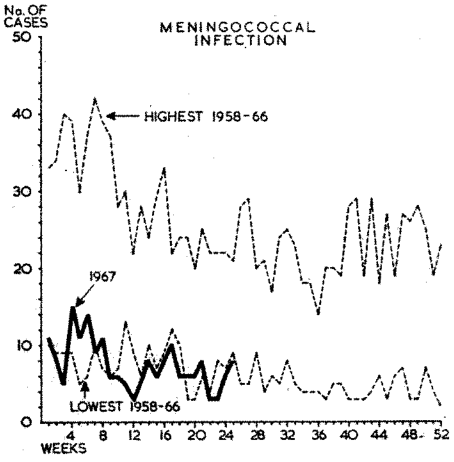
News and Notes

EPIDEMIOLOGY

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of acute poliomyelitis and meningococcal infection in England and Wales. Figures for 1967 are compared with the highest and lowest figures for each week in the previous years shown.





Infectious Diseases

Areas where numbers of notifications were high in the latest two weeks for which figures are available.

	Week Ending 23 June	Week Ending 30 June

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending **24 June** (No. 25) and corresponding week 1966.

Figures of *cases* are for the countries shown and for Greater London. Figures of *deaths* and *births* are for the whole of England and Wales (London included) Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The Table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

PARLIAMENT

Hospital Treatment Facilities for Drug Addicts

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The extent to which hospitals will be ready to treat drug addicts when the Dangerous Drugs Bill, with its restrictions on prescribing except by licensed medical practitioners, has become law is still the subject of persistent questioning to Government departments. There was more of it when the Bill was discussed on the committee stage in the House of Lords on 5 July.

LADY PHILLIPS, speaking for the Government, told the House that the Government had it in mind to bring the notification regulations into operation in the autumn. Before then it hoped to have set up a panel to advise doctors who were in doubt whether a patient was an addict; to have introduced in connexion with the central records of addicts a special scheme for the identification of heroin addicts which would be used by the treatment centres; and to have introduced, also in the treatment centres, new precautions against the misuse of prescriptions.

It was hoped, she continued, to bring the prescribing regulations into operation early next year. Before then adequate treatment facilities must be provided, arrangements made for the transfer of addicts from general practitioners to hospitals, and for the licensing of doctors at treatment centres to administer, prescribe, or supply restricted drugs.

Assurances Sought

All this came at the end of a general discussion of the operation of the Bill begun by **LORD SANDFORD**. Accepting the special case for starting with heroin and cocaine, he nevertheless contested an impression he thought was gaining ground that other drugs were somehow less dangerous, and he asked the Government to make a public authoritative statement now about the dangers of cannabis and other drugs not included in the Bill.

He also wanted firmer assurances about the provision of treatment centres—the linchpin of the whole scheme—and plans for ensuring the provision of rehabilitation hostels to match them. The Minister of Health had said in the Commons on 3 July that inpatient services for heroin addicts were available in all regional hospital board areas and outpatient services in 12. He hoped it was true, but what did the services consist of; how many addicts were receiving regular treatment; when would the centres be able to cope with the 650 heroin addicts known to the Home Office in January of this year. If a doctor telephoned a hospital and asked that an addict be admitted, could he be accepted straightaway?

There would be a critical stage when the Bill became law and before the regulations were brought into force. The handful of dedicated general practitioners doing their best to treat these demanding patients believed their right to prescribe for heroin and cocaine addicts would be taken away; the Minister had stated that general practitioners would not be licensed under the regulations. Was it sensible to jettison all the skill and experience that had been built up? It was not readily available in the hospitals. There was good reason for considering their point of view, to see whether it was possible to find some framework in which they could co-operate with the treatment centres.

LORD AMULREE, carrying this a stage further, asked if a consultant psychiatrist treating a patient would be allowed to continue treatment, or if the patient would be automatically transferred to a treatment centre. **LORD SEGAL** took the view that the problem was of such extreme urgency that the first emphasis must be on control by means of notification. He suggested that licences should be issued as liberally as possible, so that an appreciable number of general practitioners who already had experience with addicts might receive them. It might be necessary to grant them on a temporary basis, to tide over the immediate phase when the number of notifications might be so high that the specialists designated and licensed by the central authority might not be sufficient to cope with the flood.

Study of Cannabis

LORD STONHAM, Under Secretary for the Home Office, deprecated any suggestions that cannabis was not a serious question. There was probably more traffic in and consumption of cannabis than of any other drug under international control. Smoking it had become extensive only recently. Before the war it was no problem; last year there were over 900 convictions. It was a drug about which there was a considerable area of "no knowledge." The Government were convinced that the essential starting point before action was a careful assessment of all that was known about the drug. Two months ago an advisory committee on drug dependence under the chairmanship of Sir Edward Wayne began a study of the pharmacological, legal, and social aspects. Until they had reported it was premature to consider what, if any, amendment should be made to the law. But the study was evidence of a determination to ascertain the facts and do whatever was necessary.

Hospital Memorandum

LADY PHILLIPS, who speaks for the Ministry of Health, repeated the assurances previously given that regulations prohibiting prescription by general practitioners would not be brought in until the Ministry were satisfied that hospital facilities were adequate. The memorandum of guidance issued to hospital authorities last March recommended inpatient treatment for the withdrawal of heroin in small groups, not more than 12, in mental illness hospitals or psychiatric units of general hospitals. It might be considered desirable to treat separately heroin addicts and others, or to separate younger heroin addicts from older ones. Arrangements for treatment were a matter for clinical discretion.

For addicts unwilling to accept withdrawal treatment, expected to be the majority, the memorandum recommended outpatient services. The load must be shared, and the plan was for psychiatric hospitals in and around London to provide most of the inpatient services, and for the teaching hospitals and psychiatric departments to provide most of the outpatient services, though some hospitals would provide both. There were now in operation 11 outpatient clinics in London, and plans for four others were under urgent consideration.

Describing the results which the Ministry hoped to see, she said that authority to administer, prescribe, and supply heroin would be confined to licensed doctors at a relatively small number of centres. Addicts would be checked against central records to ensure they were not being treated at more than one centre. New precautions would be adopted to prevent the misuse of prescriptions dispensed by retail chemists.

The addict unwilling to accept withdrawal treatment would usually be invited to enter hospital for a short period in which dosage could be accurately assessed. By these means excessive prescribing should be reduced, and perhaps eliminated, and the spread of addiction checked. There was clearly a need for some form of treatment after withdrawal in hospital, but the form it should take was less certain.

The problem of providing effective rehabilitation was very difficult. The Minister had arranged two conferences on the subject—one with psychiatrists, and the other with voluntary bodies and local authorities. There seemed to be support for the idea that after completing withdrawal treatment addicts would benefit from staying in hostels where they could receive some social support and medical supervision. It also seemed, unfortunately, that only a small minority could be expected to complete a period of rehabilitation. In view of this it seemed appropriate to make no initial large-scale provision of hostels, but instead to build on the experience of a few experimental hostels. Several of these had been started by voluntary bodies, and the Government welcomed this initiative.

New Clauses

The new clauses authorizing the Home Office to impose a unified code for the safe-keeping, record keeping, and packaging of drugs (hard and soft), and giving the police powers of search on suspicion, were added to the Bill.

MEDICAL NEWS

University of Birmingham

Professor R. B. HUNTER, F.R.S.(Ed.), has been nominated Vice-Chancellor and Principal of Birmingham University in succession to Sir ROBERT AITKEN, who is to retire in September next year. He is professor of materia medica, pharmacology, and therapeutics at St. Andrews University. Professor Hunter, who is 52, graduated at Edinburgh University in 1938. After service in the R.A.M.C. he was appointed lecturer in therapeutics at Edinburgh and assistant director of the Edinburgh Postgraduate Board for Medicine. In 1948 he went to his present post at St. Andrews. He was dean of the faculty of medicine from 1958 to 1962 and is director of postgraduate medical education. In 1965 he was visiting professor of medicine in the postgraduate school of the University of Adelaide. He is a member of the General Medical Council, a member of the Committee on Safety of Drugs (chairman of the Clinical Trials Subcommittee), and an editor of the *Quarterly Journal of Medicine*. Since 1964 he has been a member of the University Grants Committee and last year he was appointed chairman of the medical subcommittee.

Appointments to Chairs

Dr. D. B. BREWER has been appointed to the first chair of morbid anatomy in the pathology department at the Medical School, Birmingham. Dr. Brewer graduated M.B., B.S. at the Welsh School of Medicine in 1943. After service in the R.A.M.C. he worked in the pathology department at Cardiff, first under Professor J. B. DUGUID and later under Professor J. GOUGH. He obtained the M.D.(Lond.) in 1947. In 1948 he was appointed lecturer in pathology at Birmingham University, and after two years as lecturer with the late Professor J. R. SQUIRE in the department of experimental pathology he became senior lecturer in the pathology department in 1953 and reader in 1955. He is a founder member of the College of Pathologists and was admitted to fellowship in 1965.

Professor P. G. H. GELL has been appointed to the chair of experimental pathology at Birmingham University from 1 August. He has held a personal chair in immunological pathology in the same department since 1960. Professor Gell was educated at Stowe School, Trinity College, Cambridge, and University College Hospital Medical School. After qualifying he worked in the Emergency Public Health Laboratory Service and later on the staff of the National Institute for Medical Research. He was appointed reader in experimental pathology in 1948. A research group in basic immunology was established in the department under Professor Gell's direction by the Medical Research Council in 1964 (see *B.M.J.*, 15 August, p. 456).

Naming of Chairs

The chair of obstetrics and gynaecology has been named the Lawson Tait Chair of Obstetrics and Gynaecology. The chair of paediatrics and child health has been named the Leonard Parsons Chair of Paediatrics and Child Health. The chair of pathology has been named the Leith Chair of Pathology. (The Leith chair was previously that of experimental pathology, held by the late Professor J. R. SQUIRE.)

Health Service Report

There was a " striking measure of success " in 1966 according to the Ministry of Health report for that year (Cmnd. 3326, H.M.S.O., 19s. net). Evidence is found in the hospital building programme, use of hospital resources, the " vigorous growth " of the local authority health and welfare services, and the family doctor service.

In general practice the number of prescriptions increased by 7.2% and their cost by 9.8%. At the end of the year there were 536,000 patients waiting for admission to National Health Service hospitals as inpatients, the majority seeking admission to surgical and gynaecological departments. Despite progress, the average length of stay in beds for the acutely ill remained " appreciably higher " than in many other advanced countries, and there was marked variation between hospital regions in England and Wales.

A further fall (183) is recorded in the number of principals providing full general medical services. On the other hand, during the year ended July the number of newly qualified doctors increased by over 130. In the medical schools the intake rose to a level about 30% higher than in 1960–1. Attendances at refresher courses went up from 7,156 to 8,953, some 5,740 doctors taking part. The Ministry's Regional Medical Officers made 1,300 visits to discuss prescribing costs, 100 more than the previous year.

Eight new health centres were opened, giving a total of 31 in England and Wales ; 13 were being built and plans for a further 27 were approved. Though the number of hospital beds fell by 1,468, inpatients treated rose by 2%. A total of 717 more beds were made available for geriatric and chronic sick cases. The number of medical laboratory technicians trained in techniques for testing for cancer of the cervix increased from 382 to 545. By the end of the year 112,849 women a month were being screened, compared with 64,000 a month in 1965. On hospital building the report comments that the most important single lesson learned from the previous five years' work was that the rate of achievement depends directly on the intensity with which planning and design manpower is utilized. The ability to manage hospital building on a national scale, it observes, is the envy of many other countries.

Expenditure on the health and welfare services for the 1965–6 financial year was £1,241m., over 4% of the national income. The cost for the current year is put at £1,367m.

University of Newfoundland Medical School

Dr. IAN E. L. H. RUSTED has been appointed dean of the new medical school at the Memorial University of Newfoundland. He is physician to the General Hospital and chairman of the department of medicine at St. John's and director of the Memorial University medical research unit. Dr. Rusted received his training at Memorial University College, as it then was, Trinity College, University of Toronto, and Dalhousie University. He took the M.Sc. at McGill, and has held a fellowship in medicine at the Mayo Clinic. He is a Fellow of the Royal College of Physicians (Canada), a Fellow of the American College of Physicians, and Vice-President - elect of the Royal College of Physicians and Surgeons of Canada. His main research interests are thyroid disease and hypertension. He has also worked on mitral-valvular disease and diabetes.

Lord TAYLOR has taken office as President of the University (see *B.M.J.*, 1966, 18 June, p. 1550).

New Research Building at Hammersmith

A building to house the Medical Research Council's cardiovascular research unit was opened on 10 July at the Royal Postgraduate Medical School. It has been presented by Mr. JOSEPH COLLIER in recognition of the benefit he has received from medical science. In a short speech after visiting the building Mr. ANTHONY CROSLAND, M.P., Secretary of State for Education and Science, referred to the work of the unit as " extraordinarily impressive."

Kent Postgraduate Medical Centre

On 8 July, following a dedication by the Lord Bishop of Dover, Professor Sir JOHN MCMICHAEL, F.R.S., opened the new building of the Kent Postgraduate Medical Centre at Canterbury. The Centre, which is on the main drive of the Kent and Canterbury Hospital, occupies a total area of 5,400 sq. ft., and together with equipment cost £26,000. Besides offices and a kitchen, it contains a common room, a museum–demonstration room, the Linacre library, a tutorial room, and the Harvey lecture hall. The last two rooms can be thrown together to provide accommodation for a total audience of 140.

In his opening address, Sir John McMichael quoted Sir Francis Fraser's dictum to medical teachers: " Never let your pupils see you doing anything second-rate." Sir John reminded his audience that many of the young doctors who were taking part in programmes of vocational and continuing education at present would still be practising in the twenty-first century, and he emphasized that much of the responsibility for the competence of future doctors lay with the postgraduate medical centres attached to peripheral hospitals.

The organizers of the Centre hope that the new building will enable the already flourishing programme of postgraduate education (see *B.M.J.*, 1966, 2, 295)—which besides medicine includes dental and veterinary surgery and the related sciences—to continue and to be expanded. The opening scientific lecture in the new building, on myelomatosis by Professor Jan Waldenström, was due to be given on 12 July.

British Association of Urological Surgeons

The following have been elected officers for 1967–8: *president*, Mr. A. W. Badenoch; *vice-president*, Mr. W. S. Mack; *honorary secretary*, Mr. J. F. R. Withycombe; *honorary treasurer*, Mr. Howard G. Hanley.

People in the News

▶ Captain J. S. Cox, Royal Army Medical Corps, has had the M.B.E. conferred on him for gallant conduct in Aden.

Grants and Awards

Dr. Trevor H. Howell has been awarded the Willard O. Thompson gold medal by the American Geriatrics Society for distinguished contributions to geriatric medicine.

Coming Events

British Academy of Forensic Sciences.—Scientific meeting, "The Hazards of Modern Life," 21–22 July, Institute of Psychiatry, Maudsley Hospital, London S.E.5. Admission by ticket. Application to Secretary-General, British Academy of Forensic Sciences, 37 Welbeck Street, London W.1.

Israel Medical Association.—Congress, "Human Genetics," 1–9 August. Details from office of Seventh World Assembly of the Israel Medical Association, Beth Harofe, 1 Heftman Street, Tel Aviv.

British Council for Rehabilitation of the Disabled.—Residential seminar on rehabilitation engineering services, 4–6 August, Digby-Stuart College, London S.W.15. Details from B.C.R.D., Tavistock House South, Tavistock Square, London W.C.1.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Monday, 17 July

Institute of Laryngology and Otology.—5.30 p.m., combined staff consultation clinical meeting.

Royal Free Hospital.—5.15 p.m., Professor T. Doxiades (Athens): Modern Aspects of Amoebiasis.

Tuesday, 18 July

B.B.C.—2 Television.—1.15 p.m., medicine today: Heart Failure. (Sponsored by A.S.M.E.)

London Jewish Hospital Medical Society.—8.15 p.m., Dr. S. Weinberg (New York): Bullous Diseases of Infancy and Childhood.

Royal Postgraduate Medical School.—4 p.m., Mr. G. C. Knight: Stereotactic Tractotomy in Mental Illness.

Wednesday, 19 July

Royal College of Surgeons of England.—4 p.m., Pocklington memorial lecture by Professor L. E. Zimmerman (Washington, D.C.): Cancerous, Precancerous, and Pseudocancerous Lesions of the Cornea and Conjunctiva.

Stoke Mandeville Hospital.—(1) 12.15 p.m., Dr. R. Spalding Smith: Barium Enemas. (2) 6 p.m., Dr. A. Stephen Hall: *X*-ray Quiz.

Thursday, 20 July

Royal Postgraduate Medical School.—4 p.m., Professor T. Doxiades (Greece): Amoebiasis.

Friday, 21 July

Royal College of Surgeons of England.—3 p.m., Charles Tomes lecture by Dr. F. A. Henny (Detroit): An Evaluation of High Mandibular Condylectomy for Temporomandibular Dysfunction.

Royal Postgraduate Medical School.—(1) 10.15 a.m., Mr. J. P. M. Clark: Peripheral Surgery in Spastic Paralysis; (2) 11.30 a.m., Mr. W. H. Stephenson: Clinicopathological Conference.

Appointments

Brigden, W. W., M.D., F.R.C.P. (consulting cardiologist to the Royal Navy).

Knyvett, A. F., M.B., M.R.C.P., M.R.A.C.P. (medical superintendent, Royal Brisbane Hospital, Queensland).

Liverpool Regional Hospital Board.—C. F. Conway, M.B., F.F.A. R.C.S., D.P.H. (consultant anaesthetist to Chester Royal Infirmary); S. M. Hart, M.B., F.F.A. R.C.S. (consultant anaesthetist to Broadgreen Hospital); P. Harper, M.B., D.P.M. (consultant psychiatrist to Rainhill Hospital); Phyllis E. D'Netto, M.R.C.P.Ed., D.C.H. (consultant geriatrician to Deva and Moston Hospitals).

New Issues of Specialist Journals

Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London W.C.1.

ANNALS OF THE RHEUMATIC DISEASES

Contents of the July issue are as follows:

Immunocytology in Arthritic Joints. M. L. Barnhart, J. M. Riddle, and G. B. Bluhm.
Components of the Fibrinolytic System in Synovial Joints. D. E. Caughey and T. C. Highton.
Significance of Antinuclear Factor in Older Persons. R. F. Willkens, R. R. Whitaker, R. V. Anderson, and D. Berven.
Salivary Flow Rates and Iodide Trapping Capacity in Patients with Sjögren's Syndrome. D. K. Mason, R. McG. Harden, J. A. Boyle, M. K. Jasani, J. Williamson, and W. W. Buchanan.
Intra-articular Hydrocortisone in Osteoarthrosis. K. D. Shah and V. Wright.
Changes in the Antigenic Properties of Connective Tissue in the Skin of Embryonic Rats during Development. D. G. Scott and N. R. Rowell.
Rheumatoid Changes in the Metacarpophalangeal Region as a Cause of Bunnell's Sign. K. Vainio.
Blood Groups ABO and Rh(D) Factor in the Rheumatic Diseases. I. Stoia, R. Ramneantu, and M. Poitas.
Antiglobulin Factors in Sera from Patients with Rheumatoid Arthritis and Normal Subjects. G. Torrigiani and I. M. Roitt.
Heberden Society. Book Reviews. Notices. Abstracts.

Volume 26, No. 4. Yearly subscription (6 numbers) £4 4s., abroad £4 15s.

BRITISH JOURNAL OF INDUSTRIAL MEDICINE

Contents of the July issue are as follows:

Individual Variations in Sickness Absence. P. J. Taylor.
Mortality in a Movie Projectionist Union in Boston, 1910–64. B. G. Ferris, jun., and J. Worcester.
Physique and Serum Lipids of Young London Busmen in Relation to Ischaemic Heart Disease. R. M. Oliver.
Use of the Albino Guinea-pig to Detect the Skin-sensitizing Ability of Chemicals. M. A. Stevens.
Early Signs of Lead-exposure: A Comparative Study of Laboratory Tests. A. de Bruin and H. Hoolboom.
A Cooling System for Impermeable Clothing. J. P. Gleeson and J. F. Pisani.
Effects of Pulsed Currents on Respiration and the Heart. W. R. Lee, S. Zoledziowski, and S. Temiyachol.
Investigation of a Minor Asbestos Hazard. M. C. S. Kennedy and R. Routledge.
Miscellanea:
  Protection of Employees with Defective Vision. J. P. W. Hughes and M. A. Cooke.
  Apparent Onset of Coal-workers' Pneumoconiosis after Leaving the Mines. N. K. Coni.
  A New Method for Calibrating the Kofranyi-Michaelis Respirometer. C. T. M. Davies and D. S. Shirling.
Book Reviews.

Volume 24, No. 3. Yearly subscription (4 numbers) £3 3s., abroad £3 10s.

Universities and Colleges

BIRMINGHAM

The title of university clinical lecturer has been conferred on the following: Mr. R. L. Edwards, part-time consultant obstetrician and gynaecologist to the United Birmingham Hospitals, from 1 May 1967; Dr. J. Insley, part-time consultant paediatrician to the United Birmingham Hospitals, from 1 March 1967; Dr. R. E. Nagle, part-time consultant cardiologist to the United Birmingham Hospitals and the Regional Hospital Board, from 1 April 1967; Dr. J. Stuart, consultant haematologist to the United Birmingham Hospitals, from 1 July 1967.

The title of senior clinical tutor has been conferred on the following: Mr. M. B. Stanton, consultant ear, nose, and throat surgeon to the Birmingham and Midland Ear and Throat Hospital, from 1 January 1967; Mr. R. S. Sneath, consultant orthopaedic surgeon to the Royal Orthopaedic Hospital and Selly Oak Hospital, from 1 October 1966.

Appointments.—Mr. J. R. Geddes and Mr. D. A. K. Woodward (clinical tutors in surgery for dental students).

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the College held on 12 May, the following candidates having passed the requisite examinations were admitted Fellows:

P. M. Atkinson, H. A. M. H. Badran, D. L. Bailey, R. S. Bartholomew, S. K. Beshara, S. L. Biddulph, W. E. Birkenstock, W. N. F. Boughey, G. A. Bunch, V. W. Burton, D. W. Cairns, J. M. Cairns, I. B. Chakravarti, A. Wing-Tai Chan, M. A. Choudry, A. A. Chowdhury, P. I. Condon, B. Cruickshanks, Abdul-Razzak S. Dabbagh, K. R. De, Caroline M. Doig, J. B. Garston, A. D. Garud, Y. V. Ginde, L. H. Grundlingh, M. A. Hamoud, G. El D. M. Hamza, A. Higham, N. J. B. Hitchcock, J. A. B. Hokin, E. G. Holmes, E. M. Holt, B. N. Irani, S. Jamal, S. Jawaheer, R. F. Jones, C. P. Joseph, E. Kabir, A. M. Karmody, B. Z. Katalinic, (Mrs.) Mahmooda Khan, M. I. Khan, P. E. Kiely, U. T. Kosalge, (Miss) Piloo D. Kotwal, T. D. Kretzmar, W. S. P. McGregor, R. A. McWilliam, F. Ma, C. J. Magarey, N. Majumdar, M. J. R. Marsh, G. S. Martinez, M. A. Matin, T. S. Maung, M. A. Mirza, R. Mustafa (Al Kattan), K. K. Nair, M. Y. Najjar, J. P. O'Brien, C. A. Quick, K. C. Rankin, W. J. C. C. Rich, E. S. Rosen, R. C. Sahu, S. Selvarajah, J. H. Shah, K. Shanmuganathan, G. A. Sheikh, M. J. Simcock, J. T. Snow, R. S. Sodhi, J. A. Spencer, E. A. Sue-A-Quan, J. J. Talati, M. Tasleem, Ll. A. Toft, B. A. Trevitt, M. J. Troy, A. R. Undre, A. J. V. M. Van Merwyk, C. S. Viswanathan, S. M. Vitharana, A. C. Warr, R. H. Weeks, B. Wheatley, J. Winch, J. D. Wisheart.

Deaths

Roberts.—On 5 July 1967 in hospital, Kenneth Roberts, L.M.S.S.A., D.A., of Droitwich, aged 77.

Correction

The appointment of Dr. Edward Cooper at Leeds University, announced in the issue of 1 July, is the Harold Mackintosh Professor of Cancer Research and Director of Cancer Research.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON W.C.1. TELEPHONE: 01-387 4499. TELEGRAMS: *Aitiology, London W.C.1.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.
Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.
ADVERTISEMENT AND SUBSCRIPTION ORDERS should be addressed to The Manager at B.M.A. House, London, or at 415 Bourke Street, Melbourne, Victoria, Australia.
MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A. Scottish Office, Drumsheugh Gardens, Edinburgh.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY 22 JULY 1967

Pointers

Bristol Annual Meeting
Scientific Proceedings (pp. 227–236).
A.R.M. (*Supplement*, pp. 69–98)
Lord Cohen's Gold Medal (*Supplement*, p. 99).
Leader (p. 192), letter (p. 245).

Management of Ulcerative Colitis: Favourable results of early radical surgery reported by Professor J. C. Goligher and colleagues (p. 193). Leader at p. 188.

Dwarfism: Acute metabolic response to injected human growth hormone was greater in patients with hypopituitarism investigated by Dr. K. E. W. Melvin and colleagues (p. 196). Leader this page.

Chronic Intestinal Ischaemia: Mr. J. Kennedy Watt and colleagues report successful revascularization in proved cases (p. 199).

Chronic Bronchitis: New long-acting sulphonamide is more valuable in prophylaxis than in treatment of acute exacerbations, according to Dr. A. Pines (p. 202).

Augmented Histamine Tests: Mr. R. J. Abernethy and colleagues found differences in expressing results of test responses unlikely to alter conclusions derived therefrom (p. 205).

Dangers of Thorotrast: Dr. A. O. Langlands and colleagues consider progressive loss of splenic function may occur as a result of this irradiation (p. 206).

Unexplained Digital Ischaemia: Mr. P. R. Hawley and colleagues demonstrated occult neoplasm in six patients presenting with "Raynaud's disease" (p. 208).

Unusual Sunburn: Dr. A. E. A. Ridgway reports retinopathy from eclipse exposure (p. 212).

E.S.R. and the Pill: Dr. J. Ll. Burton found the rate raised in healthy women (p. 214).

Radiation Sickness: Pyridoxine gave good results in the hands of Dr. H. Mattie and colleagues (p. 215).

Case Reports: Englemann's disease (p. 217). Phenindione-induced neuropathy (p. 218).

Medicine Today: Article on heart failure complementing B.B.C. 2 television programme (p. 219).

Today's Drugs: Special article giving advice on prescribing in pregnancy (p. 220).

Pertinax: Without Prejudice (p. 237).

Ortho-dianisidine: Suspected carcinogenic properties for laboratory staff. Letter (p. 238), leader (p. 189).

National Kidney Centre: Letter from Dr. S. Shaldon, the medical director (p. 241).

Abortion: Mr. Steel's Bill through Commons (p. 250).

Children of Short Stature

"Why is he so short? Why won't he grow?" These are questions frequently asked by parents and not always easy to answer. Recently D. W. Smith has given illustrated descriptions of 52 syndromes in which short stature is a feature.[1] The diagnosis of a few of these conditions requires no more than the eye of the experienced clinician who has seen the condition previously, and in future it may often be made with the help of a computer. But sometimes no firm diagnosis can be made even after many investigations.

Conditions for which treatment may be available must be specially sought first. They include malnutrition, depression of appetite due to emotional deprivation, malabsorption, congenital heart disease, and chronic kidney disease. Mild degrees of hypothyroidism may be difficult to diagnose and should be considered in any child with failure of growth. Excess of corticosteroid leads to retardation of growth and is more often due to administration of these hormones than to Cushing's syndrome.

Children with chromosomal disorders such as Down's syndrome (mongolism) and gonadal dysgenesis are short, and in the investigation of a girl of short stature a buccal smear to determine the sex chromosomes is an essential and simple investigation. When, however, gonadal dysgenesis is associated with chromosomal mosaic—that is, cells with different complements of chromosomes—the buccal smear may be normal and the diagnosis can be made only by further investigation of the chromosomes.

In a few children failure of growth antedates birth. They have a birth weight below that expected for the period of gestation and have been called "low birth weight dwarfs." No doubt there are many reasons for retardation of intrauterine growth,[2] and in the individual child the condition often remains unexplained.

In practice the diagnosis of most of the conditions so far mentioned can usually be made or excluded on the basis of a careful clinical history, a physical examination, and with the help of a few carefully selected investigations. Once they have been excluded, the clinician has to decide whether his patient is a normal child but of short status, or has hypopituitarism, or falls into the group of children whose failure of growth cannot be adequately explained.

When hypopituitarism is due to a demonstrable lesion of the central nervous system, such as a craniopharyngioma, the diagnosis is usually but not always easy. But in the idiopathic type it is difficult and in the past was often delayed until, at the expected age, failure of sex hormone secretion gave additional evidence of pituitary failure. Now that human growth hormone is available for treatment, earlier diagnosis has become important. Supplies of this hormone are scarce because it cannot at present be synthesized but has to be extracted from pituitary glands obtained at necropsy. It appears to be of little value in the treatment of short children whose failure of growth is not due to deficiency of the growth hormone. Correct diagnosis is therefore important so that hormone will be given only to children likely to benefit from it.[3]

The June issue of the *Archives of Disease in Childhood* contains four papers on the diagnosis of hypopituitarism as well as an annotation by A. Prader,[4] who with his colleagues in Zurich has contributed so much to the subject. The first three papers come from the Institute of Child Health in Birmingham and evaluate critically certain laboratory tests.[5–7] The fourth paper comes from the Institute of Child Health and the Hospital for Sick Children, Great Ormond Street, London,[8] and stresses the importance in diagnosis of accurate and repeated measurements of height, weight, skeletal maturity, and skinfold thickness.

These studies, and the study by Dr. K. E. W. Melvin and his colleagues from the Royal Postgraduate Medical School at page 196 of the *B.M.J.* this week, show that at present there is no single reliable diagnostic test for deficiency of growth hormone. A battery of tests is required, and some of these are time-consuming and difficult for the patient, the nurses, and the laboratory staff, and ideally should be undertaken only in a metabolic unit. The best and most simple guide in reaching a decision whether to submit a short child to such investigations is the growth curve.[9] Accurate recording of height and weight of these children at regular intervals is essential. Too often these measurements are done inaccurately by inexperienced staff, with unreliable height measures and balances. The charts prepared by J. M. Tanner and R. H. Whitehouse, of the Institute of Child Health, University of London, are satisfactory for the purpose of recording these data, and the height of children in whom a diagnosis of deficiency of growth hormone has to be entertained will fall well below the third centile. In idiopathic hypopituitarism, the growth curve begins to flatten during the first two years of life, and height deviates progressively from the third centile. In small normal children the height is usually only just below that level and with advancing age tends to approach it or at least runs parallel to it. In the child with retardation of intrauterine growth the degree of stunting tends to be intermediate. The bone age tends to be more delayed in the child deficient in growth hormone, even without associated hypothyroidism, than in either the small normal child or the child with retardation of intrauterine growth.[8]

Though spontaneous hypoglycaemia may be a symptom of hypopituitarism, particularly in early childhood, L. Stimmler and G. A. Brown[6] found the response to insulin-induced hypoglycaemia (insulin tolerance test) to be of little value in the diagnosis of growth-hormone deficiency. In some but by no means all children with deficiency of this hormone appropriate tests will show up a deficiency of thyroid-stimulating hormone or corticotrophin (A.C.T.H.) or both, and in a few the level of serum cholesterol is raised without evidence of hypothyroidism.[5]

Probably the two most useful tests for detecting deficiency of growth hormone are the plasma growth-hormone response to insulin-induced hypoglycaemia[10] and the nitrogen-retention test during a short period of treatment with human growth hormone.[11] Stimmler and Brown[6] found that all their seven patients with hypopituitarism failed to produce an adequate increase in the concentration of growth hormone in the plasma in response to insulin-induced hypoglycaemia. However, four other children of short stature but without clinical evidence of hypopituitarism also failed to respond adequately. In other words, a normal response appears to rule out a diagnosis of growth-hormone deficiency, but an abnormal response is not absolutely diagnostic. Though in their patients the intravenous insulin test did not give rise to anxiety, it requires extreme watchfulness. The recent observation of J. J. Gagliardino and his colleagues[12] that vasopressin raises serum levels of growth hormone in normal children and adults but not in those with hypopituitarism may lead to the development of a safer test. At present only few laboratories are getting reliable results with the delicate radio-immunological assay of growth hormone.

As a single test the nitrogen-retention test is probably the most reliable, though time-consuming. Brown, Stimmler, and J. G. Lines[7] determined the nitrogen retention produced by administration of human growth hormone to 22 short children, 10 of whom had hypopituitarism. They found increased nitrogen retention in all but two of the children, but it was greater and longer lasting in the group with hypopituitarism. Dr. Melvin and his colleagues, in their study of the acute metabolic response to injected human growth hormone, also find nitrogen retention to be most marked in patients with hypopituitarism, but regard the fall in blood urea as an even more useful distinguishing feature. That the nitrogen-retention test occasionally gives misleading results has been reported by several groups of workers.[11 13] Prader and his colleagues[4] have shown that when growth-hormone deficient children are given the hormone the serum α-amino-nitrogen increases and the α-amino-nitrogen clearance decreases, presumably because of increased transport of amino-acids into the cells.

The final proof of growth-hormone deficiency comes from a significant growth spurt in response to long-term treatment with the hormone. Children whose short stature is not due to deficiency of this hormone do not respond with a sharp increase in the rate of growth. Unfortunately there are difficulties even with this therapeutic test, because some children with growth-hormone deficiency develop antibodies to human growth hormone during the first few months of treatment which block its effect.[14]

Fulminating Ulcerative Colitis

Ulcerative colitis is a common disease, of unknown aetiology and without a completely satisfactory method of treatment. Medical therapy may control an individual attack but has little apparent effect on long-term prognosis. Surgical treatment usually entails a major, if not a radical, operation on what is often a desperately sick patient. Recent careful studies of large series of patients in which the severity and the extent of the disease have been precisely defined have provided important clues to the course and prognosis of the disease, and largely as a result of these some logical approach to therapy may be indicated, especially in the immediate management of an individual attack of colitis.

F. C. Edwards and S. C. Truelove,[1] in a study of 624 patients admitted to hospital in Oxford between 1938 and 1962, showed clearly the close relationship between the clinical severity of an attack and the possibility of death in that attack. The risk rose from 0.7% in a mild first attack to 9% in a moderate and to no less than 38% in a severe first attack. In relapses the figures were respectively 0.9%, 11%, and 2%. These are the overall figures for the total period, and it is of considerable interest that the introduction of the corticosteroids in about 1952 was followed by a considerable fall of mortality in the moderate group but caused little change in the prognosis of the severe cases. J. McK. Watts and his colleagues[2] surveyed 204 patients with ulcerative colitis who presented at the time of their first admission to hospital between 1952 and 1963 and confirmed the close correlation between severity of the attack and mortality—0% in the mild, 2% in the moderate, and 8% in the severe episodes. Prognosis was also clearly related to the increasing age of the patient and the extent of disease in the large bowel.

The usual treatment in severe cases with diarrhoea, bleeding, fever, tachycardia, anaemia, and raised erythrocyte sedimentation rate is intensive medical therapy, which usually includes corticosteroids. Surgery is kept in reserve for failed medical treatment or when there is perforation or uncontrolled haemorrhage. Even in skilled hands the operative mortality in such cases is high. S. O. Aylett,[3] for example, reported nine deaths in 53 fulminating cases (17%). J. E. Lennard-Jones and A. B. Vivian[4] have recorded a rate of 31% and J. C. Goligher[5] 29% in such patients. These figures are from specialist centres, and the mortality for emergency colectomy must be presumed to be higher still in the hands of less experienced surgeons who deal only occasionally with such problems. In such circumstances a good case can be made out for emergency ileostomy or caecostomy with decompression of the colon as a simpler alternative which might tide the patient over into a more satisfactory condition for radical surgery.[6-8]

Would earlier recourse to surgery improve on the disappointing prognosis of the fulminating cases? N. D. Gallagher and his colleagues[9] from Sydney, Australia, reported on 23 patients for whom such a policy was adopted. For 22 surgical operation was performed when there was failure to improve or sudden deterioration in spite of supportive treatment. Marked dilatation of the colon, rebound tenderness, and recurrent hypotension were regarded as urgent indications for operation. There were only two deaths (9%), which compares sharply with eleven deaths in the previous 18 patients when surgery, if it was performed at all, was a heroic measure.

In this issue of the *B.M.J.* (page 193) Professor J. C. Goligher and his colleagues from Leeds report on 74 patients with severe attacks of ulcerative colitis on whom operation was performed unless there was unequivocal evidence of rapid improvement in the patient's condition on conservative treatment. This series is compared with an earlier group of 124 patients managed along more conventional lines during 1952–63. The overall mortality in the more recent series was only 1.3% in contrast with 11.3% previously. Since January 1964 there have been no medical deaths, and the operative mortality in the 44 patients requiring urgent surgery has amounted to only one case. This is in contrast with six medical deaths in 124 cases during the preceding period (a mortality of 4.8%), and the surgical mortality of eight patients (20%) in the 40 treated during the earlier period. Although Goligher and his colleagues freely admit that this is not a fully controlled therapeutic trial, the results strongly suggest that, in special centres where there is extensive experience in both the medical and the surgical approach to the treatment of colitis, early radical surgery may have considerable advantages for patients with fulminating colitis who fail to respond rapidly to thorough medical treatment.

Carcinogenic Hazard

A letter in our correspondence columns this week (page 238) draws attention to the possible dangers of substances chemically related to benzidine, itself a known carcinogen in man and animals. Ortho-dianisidine (dimethoxy-benzidine) and ortho-tolidine (dimethylbenzidine) are likewise suspect as possibly carcinogenic in man. They are used in the manufacture of dyestuffs and in some industrial and chemical laboratories.

There is a clinical suspicion, as yet no more, that tumours of the urinary tract are occurring with undue frequency among laboratory workers. It has not yet been possible to conduct epidemiological studies on makers and users of ortho-dianisidine and ortho-tolidine, because usually workers in the dyestuff industry who have come into contact with them will have had even more contact with benzidine, an extremely potent urinary tract carcinogen in man. Ortho-dianisidine and ortho-tolidine are carcinogenic in animals,[1 2] and metabolites of ortho-tolidine have been found in the urine of men who work with the substance that would appear to be very similar to the carcinogenic metabolites derived from benzidine.[3] Indeed, ortho-tolidine was listed in the Prescribed Industrial Diseases Regulations in 1953 as a urinary-tract carcinogen.[4]

Since trivial exposure to benzidine has been known to be associated with carcinoma of the urinary tract, and since this type of carcinogen cannot be said to have a "safe dose," the handling of such substances must be subjected to stringent precautions. If suitable alternative methods based on non-carcinogenic materials exist they should be adopted. Various organizations, such as the Association of Clinical Biochemists, the Government Chemist's Department, and the Water Research Association, are seeking acceptable alternative techniques to those in current use which are based on the carcinogenic aromatic amines, and it would be helpful if information on the techniques could be collated and published.

The problem extends further back than the laboratory use of the reagents, for such materials must already have been manufactured, purified, and packed.

The Carcinogenic Substances Regulations, 1967,[5] have been laid before Parliament, and unless annulled will come into force on 9 December 1967. They will, however, apply only to places covered by the Factories Act, 1961,[6] and will not therefore directly affect research workers, who will not be required by law to submit to a medical examination. The relevant part of the medical examination to be applied to workers who do come under the Act is the requirement to submit a specimen of urine for exfoliative cytological screening every six months. In general it seems unlikely that research workers have been at sufficient risk to warrant such a procedure, but the advice given to inquirers by the Chester Beatty Research Institute is worth repeating here:

"Although it is not possible to say that there is a level of exposure to the carcinogenic aromatic amines below which there is no risk, the hazard to trained laboratory workers must be small, and we do not recommend that such people should be asked to undergo urine screening unless they themselves have read of the risk and become worried, in which case the facility should be provided, and the test carried out at six-monthly intervals at least for the rest of their lives if they so wish." The Harlow Industrial Health Service and the Chester Beatty Research Institute have issued a pamphlet entitled, "Precautions for Laboratory Workers who Handle Carcinogenic Aromatic Amines,"[7] and it is recommended that all laboratory workers become familiar with these precautions and observe them.

Haematology Automated

Automated procedures have been developed and used in industry for many years on an ever increasing scale. More recently they have been introduced into hospitals, particularly in the clinical chemistry laboratories. Now they are spreading into the other branches of clinical pathology, notably haematology.

Automation in haematology formed the theme of a symposium held at the XIth Congress of the International Society of Haematology in Sydney last August. A report of its proceedings has now been published[1] and provides an instructive account of the ways in which work in the haematological laboratory is beginning to be automated. The combination of more work and fewer technicians has spurred the development and application of automation. At the simplest level are machines for mixing blood samples and for automatic staining. There are automatic pipetting devices, electronic cell counters, and continuous-flow devices for estimating haemoglobin, counting cells, and determining blood groups. Machines can indeed provide an integrated system for the processing and analysis of specimens and the storage and reporting of data by computer.

Electronic cell counters are now widely used for counting leucocytes and erythrocytes and in all large laboratories have supplanted manual procedures. The most commonly used instrument, the Coulter counter, operates on the difference in electrical conductivity between blood cells and their suspending medium. A cell passing through the electrical field of an aperture causes an increased resistance, which produces a change in voltage. This voltage signal is converted into a digital count by a computer, and it also provides a measure of cell size. Counting time is 10–20 seconds, and, provided the samples presented to the machine are satisfactory, the results are accurate and highly reproducible. Greater speed and reliability make electronic cell counting generally superior to manual methods for leucocytes and erythrocytes. For counting leucocytes the red cells are first removed by lysis with saponin, but for erythrocyte counts the presence of white cells is unimportant because the latter usually comprise less than 1% of the cell population. The enumeration of platelets by electronic counters has not been entirely successful, and more reliable instruments are required.

Haemoglobin is now determined photometrically as haemiglobin-cyanide (cyanmethaemoglobin), and this procedure can be automated. Electronic methods based on conductance principles are available for determining packed cell volume. More recently, automated electronic systems have become available which will simultaneously count leucocytes and erythrocytes and measure haemoglobin concentration and the packed cell volume. The results can then be printed out in figures. With these more complex machines complete blood counts (with the exception of the white cell differential count) can be obtained rapidly at the rate of 40 an hour.

For ABO grouping by machine the cells are tested simultaneously with anti-A, anti-B, and anti-A+B (to identify the weak subgroups of A), and for Rh typing with anti-D and anti-CDE; the plasma is tested with A, B, and O cells. To increase the sensitivity of the process the red cells are treated with bromelin, a proteolytic enzyme, and formation of rouleaux is induced with polyvinylpyrrolidone (P.V.P.). The treated samples flow through a T-piece and the agglutinated cells are decanted through the lower limb, whence they are propelled on to a moving filter-paper strip on which each blood group is recorded as a line of agglutinates. Samples can be tested at the rate of 120 an hour, and the paper strip can be stored as a permanent record.

The antibody-screening machine is similar in principle to the blood-typing machine. Enzyme-treated red cells containing known antigens are mixed with the test sera and P.V.P. and any agglutinates formed are selectively removed. The residual red cells are haemolysed and the liberated haemoglobin is measured in a continuous-flow colorimeter, the result being recorded on moving paper by a pen recorder, which produces a series of peaks. If no agglutination has taken place all the cells will be haemolysed and the resulting haemoglobin solution will impede the transmission of a light beam (zero transmission). Antigen–antibody reactions will cause the removal of cells as agglutinates, and the haemoglobin solution derived from the unagglutinated cells will be relatively weaker and will allow increased transmission of light. This will be recorded as a peak of variable height depending on the strength of the antibody. While the machine for blood grouping appears to be reliable, that for antibody screening and identification, at least in its present state, is less reliable and requires further improvement. However, for measuring amount of antibody—for example, anti-D—the machine is very sensitive, and it may be useful in predicting the severity of haemolytic disease of the newborn.

Automated techniques have also been developed for measuring the osmotic fragility of red cells and for determining some red cell enzymes, such as glucose-6-phosphate dehydrogenase and pyruvate kinase: deficiency of these enzymes accounts for many cases of non-spherocytic congenital haemolytic anaemia. These methods probably have little place in most routine laboratories but may be more useful for research purposes and for population surveys. The automation of serum vitamin-B_{12} assays should be possible now with radioisotopic methods, the requirements being automatic pipetting and an automatic gamma-ray counter.

---

[1] *Brit. J. Haemat.*, 1967, **13**, Suppl., ed. S. M. Lewis.

While the automated procedures for blood counting are of great value, it remains important not to neglect the study of cell morphology in blood films. All haematologists are familiar with cases in which the blood count was normal but examination of the blood film showed a significant abnormality which led to early diagnosis or to recognition of a condition which would otherwise have been overlooked. It is possible that devices will be developed for automating examination of blood films. But meanwhile it is important not to become lulled into a false sense of security by figures flowing fast and furiously from the clinical laboratory. In the proper use of laboratory tests and the correct interpretation of the results, with its bearing on rational diagnosis and treatment, the haematologist must play an even greater part.

Finally, there is the question, Who shall become fully automated ? All laboratories have some degree of automation. The machines referred to above are expensive. For instance, a multichannel blood-counting and blood-grouping machine costs £5,000 to £6,000. Only the larger hospital laboratories with a big work load could justify their possession—though even if the need exists there may not be the money to buy them. The blood-grouping machine would, for routine purposes, best be sited in a regional transfusion centre, where large numbers of samples are handled. All these matters and more, such as the continued need for even more skilled and psychologically suitable technicians to supervise the equipment, are dealt with in the proceedings of the symposium on automation in haematology,[1] which should be of interest to all workers in this important field.

Hereditary Malignant Melanoma

Cutaneous malignant melanoma may arise either from a pre-existing naevus or else as a result of spontaneous malignant change in the melanocytes present in the basal layer of the epidermis. Little is known about the aetiology of the condition. There is no factual basis for the traditional view that mechanical trauma is a predisposing cause. Sunlight may be of some importance, for the tumour occurs most frequently on the exposed parts, and is seen more often in fair-skinned people living in hot climates than in those domiciled in temperate countries.[1, 2] Extremely rare in childhood, the disease has its greatest incidence in later adult life. Though naevi darken during pregnancy, there is no evidence that they are unusually liable to undergo malignant change during this period.[3, 4]

That malignant melanoma of the skin might have a hereditary basis was first suggested in 1952, when E. P. Cawley described the condition in a father and two of his three children.[5] Since then there have been a number of case reports of melanoma occurring in several members of a family.[6-10] D. E. Anderson and his colleagues have recently investigated 22 such families,[11] and have noted a sufficient similarity in the cases to warrant the recognition of a special category of hereditary malignant melanoma. In one family the tumour developed in fifteen individuals.

The noteworthy features of this type of malignant melanoma, apart from its familial incidence, are the youthful age at which it occurs and the tendency for multiple primary lesions to develop. In these respects it resembles other hereditary neoplastic conditions—for example, polyposis coli, Gardner's syndrome, and xeroderma pigmentosum. In Anderson and his colleagues' series the average age at which the condition was diagnosed was about 40 years, whereas the sporadically occurring melanoma appears more commonly about a decade later. In about 20% of the cases of hereditary melanoma two or more primary tumours were found, a striking contrast to the frequency of 1.3 to 3% in the sporadic type.[11] The mode of inheritance is complicated. In a pedigree investigated by Anderson and colleagues the disease appeared to be transmitted by an autosomal dominant gene showing poor penetrance, but it is possible that more than one gene is involved.

An important clinical implication of these findings is that young patients with malignant melanoma should be examined for similar lesions elsewhere on the skin. A family history should be elicited, and in suspicious cases the relatives should be encouraged to undergo an examination so that early lesions can be removed as soon as possible. Indeed, it may well be that common malignant lesions of other kinds in unusually young people have a similar genetic basis, and that detailed family studies would be valuable in these cases.

Contaminated Cylinders of Nitrous Oxide

In September 1966 some cylinders of nitrous oxide were contaminated with nitric oxide.[1] Since then much information has accumulated about this matter, and the May issue of the *British Journal of Anaesthesia*[2] is devoted to a series of articles on every aspect of the problem. While much of this material is naturally of specialist interest, certain facts concern anyone who has occasion to use nitrous oxide.

The stringent standards of purity laid down by the *British Pharmacopoeia* are reprinted, and the two manufacturers of nitrous oxide in this country give details of their processes and the steps taken to ensure compliance with these standards. The important contaminant is nitric oxide. If present, it dissolves in the liquid nitrous oxide. The physical properties of these gases are such that, from a full cylinder, most of the dissolved nitric oxide emerges with the first 7% of the nitrous oxide. This fact lends support to one manufacturer's practice of over-filling each cylinder and then "blowing back" the excess into the plant. Methods for the detection and determination of the higher oxides of nitrogen are described, and the practicability of using them in hospitals is discussed. Such testing might be particularly important in pipe-line installations, for here a contaminant could be delivered to several patients before any fault was suspected.

Fortunately until now the number of patients who have inhaled contaminated gases has been very small. There has been little opportunity, therefore, for anaesthetists to become familiar with the clinical picture of acute nitric-oxide poisoning and with the recommended treatment. When nitric oxide is inhaled methaemoglobinaemia, manifested by cyanosis, develops within a few minutes. At the same time intense pulmonary oedema occurs as a result of the nitric oxide dissolving in the pulmonary alveolar fluid to produce nitric and nitrous acids. This causes acute respiratory distress, or, if ventilation is being controlled, progressive difficulty in inflating the lungs. The combination of methaemoglobinaemia and pulmonary oedema results in hypoxia, the severity of which is enhanced by a concomitant acidaemia. Bradycardia is common and there is a rapid and dramatic fall in the blood pressure. The electrocardiograph may show only slight depression of the S-T segment, and any gross changes are usually terminal.

Treatment is aimed at the correction of the physiological disturbances. Oxygen is immediately administered. Intermittent-positive-pressure ventilation is almost certain to be needed. Indeed it may be regarded as mandatory, since absorption atelectasis may develop when pure oxygen is given to patients who are breathing spontaneously. High inflating pressures may be necessary for adequate ventilation, and if the distribution of gas is uneven they may result in alveolar hyperinflation. The methaemoglobinaemia is corrected by intravenous administration of methylene blue, and, since it is important to avoid overdosage, not more than 2 mg./kg. body weight is given initially. This is followed by further doses after laboratory estimation of the amount of methaemoglobin remaining in the blood. At the same time the acidaemia must be corrected by the intravenous administration of sodium bicarbonate. The oedema fluid from the lungs is sucked out and a solution of hydrocortisone and sodium bicarbonate instilled into the respiratory tract.

According to the editorial in the *British Journal of Anaesthesia*, in spite of all the efforts which have been made by the British Oxygen Co. to locate every nitrous-oxide cylinder which could come under suspicion, some have still not been traced and returned to the company's area depots for testing. Such cylinders, issued in the southern region before September 1966, are not marked with a cross on the shoulder. Anyone in this region who has such a nitrous-oxide cylinder in their possession, or who has transported such a cylinder into any other region, should communicate with the firm at once.

That British manufacturers maintain the high standards of purity demanded for medical gases is accepted by everyone using their products, and their excellent record in the past has fully justified such confidence. The prompt and effective action taken by British Oxygen when the contamination was first detected, together with the tightening-up of the precautions which they have taken to prevent and detect contamination, not only at the factory but also at bulk distribution centres, will do much to ensure the profession's confidence that this sort of accident will not happen again.

B.M.A. at Bristol

Visitors to Bristol very soon realize that its appeal comes from both its geographical setting and its history as a port. The old commercial city by the floating harbour has its original narrow streets and bars where sherry and port can be drunk from the wood, while above hang the Clifton suspension bridge and the Downs, and it was in this elegant setting that the Association's 135th Annual Meeting took place. Three previous Meetings have been held there—in 1833, 1863, and 1894—and if the President, Mr. Robert Cooke, is right in thinking that this will be the only visit the B.M.A. makes to Bristol this century then all who attended the Meeting will join him in regretting it.

Much of the success of the Meeting was due to the generous hospitality of the university and the civic authorities. The welcome reception by the local Branch and Division, the Adjourned Annual General Meeting, and the Degree Ceremony were all held in the University's Great Hall. This, an imposing building with a fine hammer-beam roof, contrasted well with the functional elegance of the new Students' Union, which housed both the Annual Representative Meeting and the Annual Scientific Meeting. The official religious service at Bristol Cathedral was particularly memorable, and this year for the first time was interdenominational —a welcome precedent. Other major occasions included the President's Reception at the City Museum, the Annual Dinner, and the civic reception at the Council House.

The scientific sessions covered a wide range of subjects but shared a theme in concentrating on practical advice which would be of value to doctors treating patients. Problems of everyday occurrence such as headache, diarrhoea, abdominal pain, and pain in the shoulder were discussed by well-known authorities in a down-to-earth way. The symposium on "Prescribing and Adverse Reactions to Drugs" was specially popular. Outstanding among the panel discussions was that on bereavement, and many practitioners will have been helped by it in dealing with this difficult and perennial problem. The plenary session on recreation towards the end of the programme stressed the importance for health of a balanced life. The Scientific and Pharmaceutical Exhibitions were well attended, and the medical films seem to reach higher standards year by year.

The social programme was full and varied. Ballet and light opera at the Theatre Royal and a B.B.C. concert were much enjoyed, and the ladies' programme organized by Mrs. J. Angell James used to full advantage Bristol's fine situation as a touring centre. Visitors will long remember excursions to several lovely mansions in the neighbourhood. The Association is much indebted to all who worked so hard to make the Meeting a success, and particular thanks are due to Professor J. H. Middlemiss, the Science Secretary, Dr. P. B. Bailey, the General Secretary, and to Dr. H. M. Golding, Chairman of the Local Organizing Committee.

The scientific proceedings are reported at p. 227 of this issue of the *B.M.J.*, and the account of the A.R.M. is concluded in the *Supplement* at p. 69.

On 13 July Sir Hedley Atkins was re-elected president of the Royal College of Surgeons of England for the ensuing year.

Early Surgery in the Management of Severe Ulcerative Colitis

J. C. GOLIGHER,* CH.M., F.R.C.S.; F. T. DE DOMBAL,* M.B., B.CHIR., F.R.C.P.
N. G. GRAHAM,* F.R.C.S., F.R.A.C.S.; G. WATKINSON,* M.D., F.R.C.P.

Brit. med. J., 1967, 3, 193–195

During the last two decades there has been a substantial improvement in the overall outlook for patients suffering from ulcerative colitis. Nevertheless, many patients continue to experience severe attacks of this disease, and the mortality from these attacks is often very high. Thus Gallagher *et al.* (1962) stated that nearly two-thirds of their patients with "fulminating" attacks of colitis during 1950–8 died; Edwards and Truelove (1963) reported a 26.8% fatality rate in all severe attacks treated during the previous decade; while Demole (1956) noted a 40% fatality rate in *all* acute attacks of colitis.

Recently we also described a large series of cases with severe attacks of ulcerative colitis, the fatality rate of which was considerable, being 9.6% in severe first attacks and 13.7% in severe relapses (de Dombal *et al.*, 1965a). In the care of these patients it had been our practice to submit practically all cases to intensive conventional medical therapy (usually including large doses of corticosteroids), for a period of 10 days or so in the first instance. Only if this regimen failed to secure a remission within that time—or if perforation or massive uncontrollable haemorrhage occurred—was surgical treatment considered.

In view of the disappointing results obtained it seemed to us that a drastic change in our plan of management was justified in the hope of reducing the high mortality. Accordingly we resolved (Watts *et al.*, 1966b) for a trial period to make surgery the sheet-anchor of our therapy in these cases and to invoke surgical aid at a very early stage of severe attacks—within a very few days of the patient entering hospital—*unless there was unequivocal evidence of rapid improvement in his condition on conservative management.*

Since this decision was taken at the end of 1963 some 74 patients have been treated by us for severe attacks of ulcerative colitis; all have been managed according to the plan outlined above. In this paper we report the results obtained and compare them with those previously reported in a similar group of 124 patients managed during 1952–63.

Clinical Material and Methods

Between 1 January 1964 and 30 June 1966 74 patients were admitted to the General Infirmary at Leeds under the care of the professorial surgical unit because they were suffering from severe attacks of ulcerative colitis. Occasionally patients were admitted twice during separate severe attacks, so that the total number of such attacks during 1964–6 was 81. Table I shows the age distribution of the patients at the time of these 81 severe attacks (and, for comparison, the ages of the patients treated for severe attacks of colitis during 1952–63). It will be seen that the composition of the two series of cases is quite similar in this respect.

Assessment of Severity of Attacks.—All attacks of ulcerative colitis were classified as severe according to the criteria of Truelove and Witts (1955), which are: *severe diarrhoea* (six or more motions a day); *macroscopic blood in the stools*; *fever* (mean evening temperature more than 99.5° F. (37.5° C.), *or* a temperature of 100° F. (37.8° C.) or more on at least two days out of four); *tachycardia* (mean pulse rate of more than 90 per minute); *anaemia* (haemoglobin 75% or less, allowance being made for recent transfusion); *E.S.R. much raised* (more than 30 mm. in one hour). Many of these severe attacks would have been labelled by some clinicians as "fulminating," but we have preferred to avoid the use of this somewhat imprecise term in assessing the severity of disease in our patients.

TABLE I.—*Age of Patient at Time of Each Severe Attack of Colitis*

Age	1952–63 (124 Attacks)		1964–6 (81 Attacks)	
	No. of Attacks	% of Total	No. of Attacks	% of Total
0–19 years	34	27·4	12	14·8
20–39 "	44	35·5	35	43·2
40–59 "	28	22·6	25	30·9
60 years and over	18	14·5	9	11·1

Plan of Initial Medical Management.—The patients were all managed according to the following regimen. On their admission to hospital an intensive course of conservative treatment was instituted; the vast majority of patients were treated with large doses of systemic corticosteroids—50 mg. of cortisone by mouth six-hourly or 100 mg. of hydrocortisone intramuscularly twice daily—often with sulphasalazine (Salazopyrin) as well (in a dosage of 1 g. six-hourly). Some of the patients received injections of A.C.T.H. (up to 100 units daily). Intravenous replacement of whole blood, plasma, and electrolytes was carried out as dictated by the needs of each individual patient (see Graham *et al.* (1967) for further details). Under this regimen several outcomes of the attack were possible—*remission* with subsidence of bowel symptoms and constitutional disturbance; *death during medical treatment*; *resort to surgical treatment with subsequent recovery* or *operative death.*

Indications for Surgical Intervention.—These were as follows: (1) persistent massive haemorrhage or the development of abdominal physical signs suggesting the occurrence of perforation of the bowel and peritonitis, particularly if associated with (2); (2) sudden deterioration in the general condition of the patient, which was usually a better guide to the occurrence of a catastrophe like perforation than were local physical signs (de Dombal *et al.*, 1965b); (3) in patients over 60 years of age, failure to show a definite clinical improvement after two to three days of conservative management; and

---

* University Department of Surgery, the General Infirmary at Leeds, Leeds 1.

(4) in younger patients, failure to show a definite clinical improvement after four to five days of intensive conservative treatment. The first two indications called for *emergency* surgical intervention, the patient being brought to operation immediately, or at latest within a few hours of the decision to resort to surgery having been reached. The remaining two indications were regarded as demonstrating the need for *urgent* surgery, the operation usually being performed within the next 24 to 48 hours.

Findings

Outcome of Severe Attacks.—The overall outcome of severe attacks of colitis in the two groups of patients is contrasted in Table II. The remission rate is shown to be slightly lower and the rate of recourse to radical surgery higher in the 1964–6 group. This was inevitable, since occasionally patients were brought to operation who might eventually have gone into remission on more prolonged conservative management, though they more frequently continued to have chronic bowel symptoms (see footnote to Table II). Nevertheless, it is noteworthy that, despite a policy the cornerstone of which was early recourse to surgery, nearly half of the patients seen went rapidly into remission on conservative treatment alone. However, the most striking feature of Table II is the clear reduction in both medical and surgical death rates which has taken place during 1964–6, and which has resulted in a fall in overall mortality from 11.3% during 1952–63 to 1.3% during the period of the present series.

TABLE II.—*Overall Outcome of Severe Attacks of Colitis*

Outcome		1952–63 (124 Attacks)		1964–6 (81 Attacks)	
		Cases	%	Cases	%
Remission		65*	52·4	38	46·9
Resort to surgery		40	32·3	43	53·1
Deaths	Under medical treatment	6	4·8	0	0
	Operative	8	20·0†	1	2·2†
	Total	14	11·3	1	1·3

*Excludes a further 13 patients who were not brought to surgery but continued for over 12 months with chronic symptoms (and hence cannot be classified as remission cases).

† Indicates percentages of patients who came to operation in each group.

Outcome of Severe First Attacks.—The mortality from colitis is always greatest during the first few months of the disease (Hurst, 1935 ; Demole, 1956 ; Edwards and Truelove, 1963). It is therefore particularly gratifying that none of the 19 patients who have been seen by us in severe first attacks during 1964–6 have failed to survive this initial attack (Table III). We have previously shown that it is in first attacks of colitis that the colon is most likely to perforate (de Dombal *et al.*, 1965b), and it is interesting to note that during 1964–6 we did not encounter a single instance of free perforation in an initial severe attack of colitis.

TABLE III.—*Outcome of Severe First Attacks of Colitis*

Outcome		1952–63 (73 Attacks)		1964–6 (19 Attacks)	
		Cases	%	Cases	%
Remission		38*	53·2	10	52·6
Resort to surgery		20	27·4	9	47·4
Deaths	Under medical treatment	2	2·7	0	—
	Operative	5	6·9	0	—
	Total	7	9·6	0	—

* Excludes 13 patients whose symptoms persisted for over 12 months but who did not come to surgery.

Outcome of Severe Attacks in Elderly Patients.—Relatively few of our patients were over 60 years of age, which means that only small groups of cases are available for analysis (see Table IV). Though we were specially ready to resort to surgical treatment in the management of this type of case in the 1964–6 period, in fact no less than half of these older patients in this latter period very rapidly improved on conservative management. Of the remainder who came to early operation none died, compared with 50% during the 1952–63 period.

Operations Performed.—Most patients were submitted to a one-stage total proctocolectomy and ileostomy (Table V). Details concerning the technique of this operation have been presented elsewhere (Goligher, 1954, 1961, 1967), and the question of choice of operative procedure has also been discussed (Watts *et al.*, 1966a). In the present series one young child aged 8 underwent colectomy and ileostomy, with preservation of the rectum. A further patient, a woman aged 29, was admitted with an extremely severe attack of residual proctitis after a previous colectomy and ileorectal anastomosis elsewhere ; she was subjected to excision of the rectum and had an ileostomy established, with uneventful recovery. The patient who had a negative laparotomy merits comment. While under intensive conservative care for a severe attack of colitis he developed tachycardia and pyrexia, together with extreme abdominal rigidity and tenderness. Perforation of the colon was suspected, but at laparotomy no such lesion was found, though the sigmoid colon was clearly the seat of active colitis. The abdomen was therefore closed without removal of the colon or ileostomy for what appeared to be a distal proctocolitis, and the patient subsequently went into remission.

TABLE IV.—*Outcome of Severe Attacks of Colitis in Elderly Patients*

Outcome		1952–63 (16 Attacks)	1964–6 (9 Attacks)
Remission		4	5
Resort to surgery		9	4
Deaths	Under medical treatment	3	0
	Operative	5	0
	Overall	8	0

TABLE V.—*Type of Early Surgery Employed*

	1952–63 (40 Cases)	1964–6 (43 Cases)
Proctocolectomy and ileostomy	32	40
Colectomy and ileostomy	6	1
Rectal excision and ileostomy	—	1
Laparotomy and closure	—	1
Other procedure	2	—

Cause of Operative Death.—There was one operative death, that of a young man of 29 who suffered in addition from cirrhosis of the liver with portal hypertension. At operation a considerable quantity of ascitic fluid was found in the peritoneal cavity. Subsequently ascitic fluid escaped through the main wound, which broke down on the ninth postoperative day and required resuture. Serous fluid continued to pour through the wound for some weeks and the patient eventually died. It is arguable that this man's death was incidental to his colitis, but, in view of the abdominal wound breakdown and of the well-known association between colitis and liver disease, we have classified this as a related death.

Discussion

In assessing the results of treatment of certain disease processes, such as severe attacks of ulcerative colitis or bleeding peptic ulcer, for which the alternatives of medical and surgical management are available, it is essential to remember that, according to the manner of selection of patients for these respective modes of therapy, success with one may be achieved largely at the expense of a high mortality with the other. The important yardstick, therefore, in gauging the value of any change of therapeutic policy is the effect on the *overall mortality*.

Accordingly, in examining the influence of our recent practice of resorting at an earlier stage to surgical treatment in severe attacks of colitis, we have paid special attention to the overall mortality, comparing it with that obtained when a tardier and more restricted use of urgent or emergency operation was in force (Table II). It will be seen that the overall fatality rate of severe attacks since this new regimen has been adopted was only 1.3%, which contrasts with 11.3% previously—a difference that is highly significant. It is also interesting to note that since January 1964 there have been no medical deaths in 81 cases and the operative mortality in the 44 cases coming to urgent or emergency operation has amounted to only one case, or 2.2%. This compares with 6 medical deaths in 124 cases during 1952–63 (a mortality of 4.8%) and a surgical mortality in the 40 cases proceeding to operation during that period of 8 cases (or 20%).

Possible Fallacies

On the face of it, therefore, it might seem that the policy of earlier surgery has achieved its objective of rendering severe attacks of colitis less hazardous; but before reaching this conclusion certain possible fallacies need to be considered.

(*a*) It may be questioned whether there has been any alteration not only in the timing but also in the type of surgical intervention during the second period. However, it will be seen from Table V that the operations employed were very similar during both periods under review and consisted usually of proctocolectomy, or colectomy, and ileostomy. There was indeed a slightly higher proportion of proctocolectomies to subtotal colectomies in 1964–6 than in 1952–63, but it is debatable in which way this might have affected the operative mortality, and inconceivable that it could have been responsible for reducing it to the extent shown in Table II.

(*b*) The possibility that a slight difference in the *form* as well as in the duration of medical treatment in these two periods may have influenced the mortality somewhat requires also to be examined. Though systemic corticosteroid therapy was consistently used in the 1964–6 period, in the first three years of the 1952–63 period corticosteroids were omitted in roughly half the cases during the conduct of the M.R.C. collective controlled trial of corticosteroid preparations in the treatment of ulcerative colitis (Truelove and Witts, 1955). But the total number of patients not receiving corticosteroids amounted to only one-quarter of the 124 in the 1952–63 group, and their mortality (12.5%) was little higher than that of the remainder of the group (11.0%). The medical therapy given to the 1964–6 cases may in general have therefore been marginally more potent than that used for the 1952–63 group; but we find it hard to believe that this slight difference could have played a major part in bringing about the striking reduction in the medical and overall mortalities of the more recent of the two groups of patients. It seems more reasonable to attribute the drop in medical mortality in this group largely to the earlier resort to surgery, and the gratifying thing is that this has been attended also by a striking fall in the surgical mortality.

(*c*) Much more serious is the criticism that the composition of the two groups of cases being contrasted in this study may be dissimilar. The influence of the age of the patient on the risks of a severe attack of colitis has been clearly shown in our previous study (de Dombal *et al.*, 1965a). Analysis of the age of distribution of the patients in our two groups of cases (Table I) shows, however, that they are roughly similar in this respect. It should be emphasized, too, that each of our two series represented nearly *all* the patients with severe attacks of colitis coming to the same hospital centre during the periods under review, the severity of the attacks having in each instance fulfilled certain well-defined criteria (Truelove and Witts, 1955).

It must be admitted that even these criteria allow considerable variation in the severity of attacks, so that there could be a difference in the proportion of particularly ill patients in the two series. Indeed, it has been our clinical impression that the virtually moribund type of case with severe acute colitis has become rather less common in recent years. But, even so, it must be pointed out that some 25 to 30 patients presented during 1964–6 in particularly severe attacks of colitis (with 10 to 15 bowel actions per day, massive rectal blood loss, fever up to 105° F. (40.5° C.), severe electrolyte disturbance, and so on); and *not one of these patients failed to survive the attack,* even though most of them were brought to radical surgery at an early stage.

Therapeutic Trial

Of course the only way to avoid uncertainties of this kind is to plan a properly controlled therapeutic trial, in which the patients are allotted in entirely random fashion to the forms of therapy on trial. Such a trial to compare the efficacy of early surgical intervention against intensive conservative treatment, including corticosteroid therapy for severe attacks of colitis, has already been proposed by us (Goligher, 1956) and by Edwards and Truelove (1963). The results which we now report with early surgery cannot therefore provide a conclusive evaluation; but, like the smaller—also uncontrolled—trial of Gallagher *et al.* (1962), they suggest strongly that in certain centres with extensive experience of colitis surgery this regimen may be the best method of treating severe attacks of this disease.

One objection to the practice of early surgery is that it may occasionally result in some patients with a short history of disease coming to urgent operation, when they might possibly have secured a remission of their severe attack on more prolonged conservative management. This objection is all the more important in view of the radical nature of the surgery involved. However, Table II indicates that the number of such patients who would eventually secure a remission is small (52% versus 46%). Moreover, our own follow-up studies (Watts *et al.*, 1966c) and those of Edwards and Truelove (1963) have shown that a high proportion of those patients who manage to survive a severe attack of colitis on conservative treatment eventually suffer further such attacks, and often end up with radical surgical treatment or succumb to their disease. The conclusion is inescapable that many of them would have fared much better if they had undergone operation at an earlier stage of their illness.

Summary

This paper presents an analysis of the outcome of 81 severe attacks of ulcerative colitis treated during 1964–6. All patients were admitted to hospital, and surgical aid was invoked at an early stage if there was no response to a short course of intensive conservative measures.

Thirty-eight patients underwent remission on conservative treatment and 43 came to operation; there were no medical deaths, but one patient died postoperatively of cirrhosis of the liver. The overall mortality in these severe attacks was thus 1.3%, which is significantly less than the overall mortality of severe attacks of colitis during the previous decade, when operative treatment was resorted to less readily.

These findings strongly suggest that early radical surgical treatment may have considerable advantages for patients with severe attacks of colitis which fail to respond rapidly to intensive medical treatment, but the possible fallacies of conclusions drawn from an incompletely controlled trial are emphasized.

Acute Metabolic Response to Human Growth Hormone in Different Types of Dwarfism*

K. E. W. MELVIN, M.B., CH.B., B.MED.SC., M.R.C.P., M.R.A.C.P.; A. D. WRIGHT,† M.B., M.R.C.P.

Brit. med. J., 1967, 3, 196–199

The effectiveness of human growth hormone (H.G.H.) in man is now well established from both the acute metabolic response (Beck *et al.*, 1958; Ikkos *et al.*, 1959; Medical Research Council, 1959) and the stimulation of growth after long-term therapy (Raben, 1962). In this paper we report the results of studies of the acute metabolic response to injected H.G.H. in different types of dwarfism and, in some of them, the relation between these responses and the levels of endogenous serum H.G.H. obtained during insulin-tolerance tests. A few of the dwarfed subjects have thereafter received long-term H.G.H. treatment in an attempt to promote growth, and the relation between this growth response and the results of the acute metabolic test has also been examined.

Patients Studied

Twenty-three patients were studied, and some of their details are shown in the Table. Seven had panhypopituitarism due to a variety of causes and 13 were dwarfed for reasons other than primary pituitary disease; the latter included six "idiopathic" dwarfs, three cases of gonadal dysgenesis, one dwarfed patient with Cushing's syndrome, and three patients on chronic corticosteroid therapy for Still's disease or asthma. The growth response of the patient with Still's disease has been reported separately (Ward *et al.*, 1966). We also report the acute response to H.G.H. in three adults suffering from carcinoma of the breast or osteoporosis, who were presumed to have normal pituitary function. The patients with panhypopituitarism were all receiving replacement therapy with cortisone at the time of the study and four were also receiving thyroxine. The only other patients who were receiving hormonal therapy during the tests were those on corticosteroids. The child with Still's disease (Case 17) was receiving 5 mg. of prednisone daily, and the patients with asthma (Cases 18 and 19) were receiving 15 and 12.5 mg. of prednisone daily respectively.

Methods

All patients were studied in the metabolic unit. They were given a standard low-calcium diet containing 68 g. of protein, 68 g. of fat, 220 g. of carbohydrate, 200 mg. of calcium, and 1 g. of phosphorus. When necessary this standard diet was altered to meet individual requirements and analysed subsequently. Total calcium intake was standardized to 2 mEq/kg. by means of supplementary calcium tablets. Chromium sesquioxide was given daily (0.5 g. t.d.s.) as a faecal marker, and the faecal analyses were corrected according to their content of this marker (Whitby and Lang, 1960). Urine was collected in 24-hour periods and analysed for nitrogen and calcium. Faeces were collected in three-day pools and were analysed for nitrogen, calcium, and chromium. The blood urea was measured daily. A five-day period for equilibration on the diet and chromium was followed by six days of basal measurements; 10 mg. of H.G.H. (Raben, 1962) was then given intramuscularly at 7 a.m. for three days, and the measurements were continued throughout the period of the injections and for the next three days.

Urine and faecal nitrogen were estimated by the Kjeldahl method (Wootton, 1964). Urine and faecal calcium and faecal chromium were measured by means of a flame spectrophotometer (MacIntyre and Brown, unpublished). The blood urea was measured in an autoanalyser. Specimens collected daily were measured in a batch at the conclusion of the study.

Serum H.G.H. was assayed throughout the course of a standard insulin-tolerance test (0.1 unit/kg.) by an immunoassay method using the double-precipitation technique (Hartog *et al.*, 1964b); the preparation of H.G.H. used as standard was the M.R.C. "A" preparation, and the lower limit of sensitivity of the method was 1–4 mμg./ml. The patients receiving corticosteroids and the boy with Cushing's syndrome were given larger doses of insulin (0.15–0.3 unit/kg.) in view of their expected insulin resistance.

Results

Acute Metabolic Response to H.G.H.

Basal measurements were made over the six days before giving H.G.H. From these a mean value was obtained for each of the measurements, against which the subsequent response to H.G.H. was compared. Though the magnitude of the response was greatest during the three days of hormone administration, the duration of action of H.G.H. was greater in the hypopituitary subjects. A better discrimination between different groups of patients was obtained, therefore, by selecting for comparison the six-day period after the first injection of H.G.H. Thus the response was measured in terms of the

difference between mean basal levels of blood urea, urine nitrogen, and urine calcium, and the mean levels of each during the six days after the first H.G.H. injection (Fig. 1).

In view of the small numbers of subjects in most of the patient categories, the main comparison has been between the hypopituitary subjects and the idiopathic dwarfs.

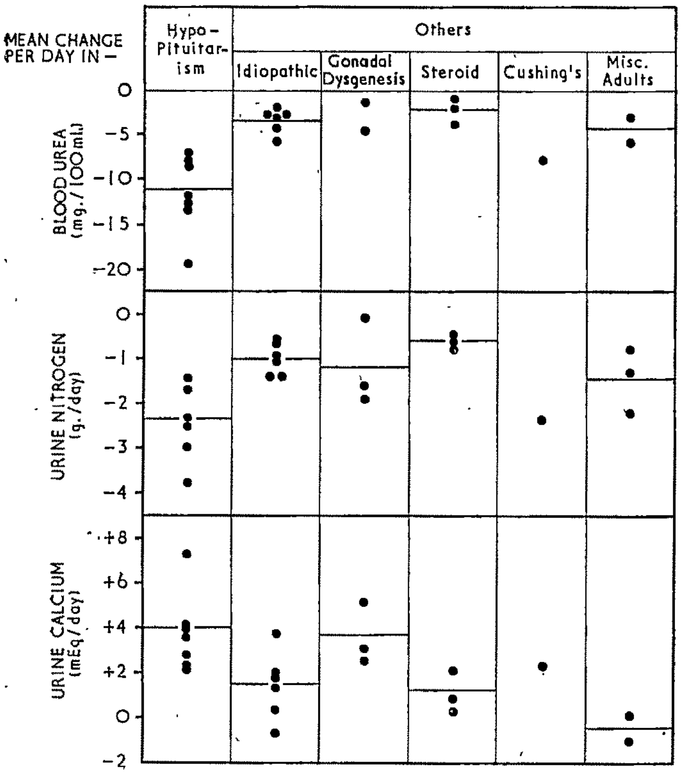

FIG. 1.—Acute metabolic response to H.G.H. (Days 1–6). Mean change per day in blood urea, urine nitrogen, and urine calcium.

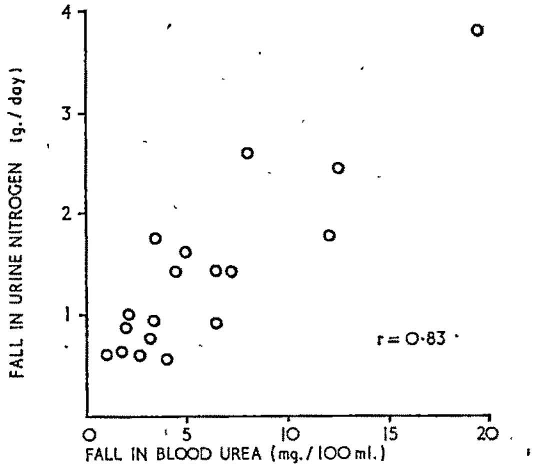

FIG. 2

FIG. 2.—Relation between changes in blood urea and urine nitrogen (Days 1–6).

Blood Urea (Fig. 1).—The fall of blood urea was greater in the patients with hypopituitarism than in the other subjects, with the exception of the boy with Cushing's syndrome. The mean fall in the hypopituitary group (11.3 mg./100 ml.) was greater than that in the group of idiopathic dwarfs (3.6 mg./100 ml.) ($P<0.01$).

Urinary Nitrogen (Fig. 1).—The patients with hypopituitarism also showed a greater fall of urinary nitrogen than did the other groups of subjects, though there was some overlap of individual values. The mean fall of 2.4 g./day in the former group was greater than that of the group of idiopathic dwarfs (1.0 g./day) ($P<0.05$). As shown in Fig. 2, there was a clear correlation between the fall of blood urea in the different subjects and the fall of urinary nitrogen. In Fig. 3 the urine nitrogen response is expressed as a function of body weight. Plotted thus, the distinction between groups of patients is less clear than when plotted in absolute figures.

Nitrogen Balance.—With a single exception, all patients developed a positive nitrogen balance in response to H.G.H. This largely reflected the changes of urinary nitrogen, and little or no change was measured in the relatively small faecal nitrogen values.

Urinary Calcium (Fig. 1).—An increase in the urinary calcium was found in the majority of the subjects. The mean rise was greater in the hypopituitary patients (3.9 mEq/day) than in the group of idiopathic dwarfs (1.4 mEq/day ($P<0.05$), though there was an overlap of individual values in these and the other groups. In particular it was noted that the patients with gonadal dysgenesis showed as large a hypercalciuric effect as did the hypopituitary subjects. A correlation was found between the changes in blood urea and urine calcium (Fig. 4).

Faecal Calcium and Calcium Balance.—No consistent changes were observed in either the faecal calcium or the calcium balance in response to H.G.H.

Relation Between Acute Metabolic Response to H.G.H. and Response of Serum H.G.H. to Hypoglycaemia

Fourteen of the subjects had measurements of serum H.G.H. performed during an insulin-tolerance test. The highest level of serum H.G.H. found during the test has been plotted against the value of the acute metabolic response to H.G.H., which provided the best discrimination between the different groups—namely, the fall of blood urea. It will be seen (Fig. 5) that there was some negative correlation ($r = -0.59$) between these figures. The subjects in whom no measurable rise of serum H.G.H. was found (which included the four hypopituitary subjects tested and the boy with Cushing's syndrome) sustained a fall of blood urea greater than 7 mg./100 ml., while in those in whom clearly measurable rises were found the fall of blood urea was less than 7 mg./100 ml.

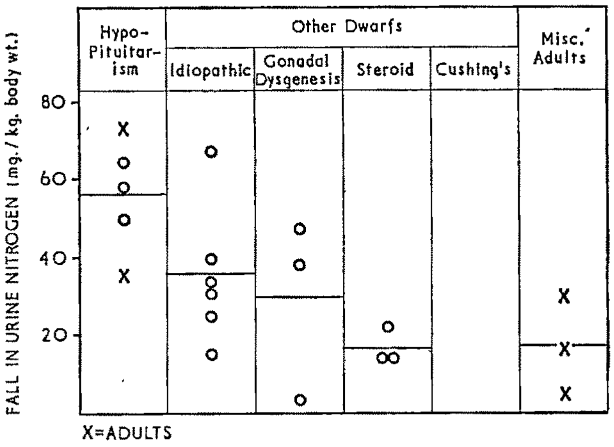

FIG. 3

FIG. 3.—Effect of H.G.H. on urinary nitrogen related to body weight (Days 1–6).

Relation Between Acute Metabolic Response to H.G.H. and Growth Response to Long-term H.G.H. Treatment

Four patients were studied for periods of at least 12 months on treatment with H.G.H. These comprised the patient with Still's disease (Case 17) and three of the hypopituitary dwarfs

(Cases 2, 3, and 4). The relation between the fall of blood urea found during the acute metabolic test on these patients and the long-term growth response is shown in Fig. 6. It will be seen that three of the patients increased their rate of growth by more than 4 cm./year during H.G.H. treatment and that all three had shown a marked fall of blood urea. The fourth patient showed no acceleration of growth with chronic H.G.H. therapy and had sustained a fall of only 4 mg./100 ml. during the acute metabolic test.

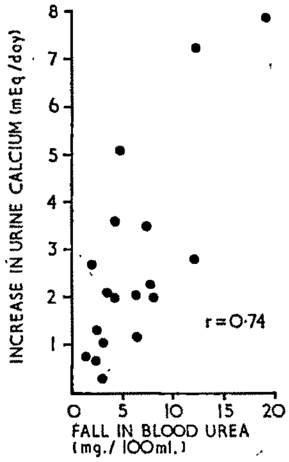

FIG. 4

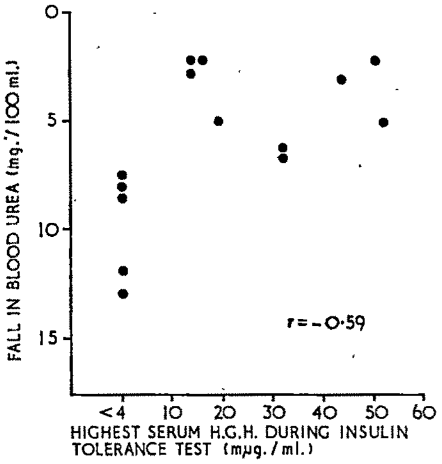

FIG. 5

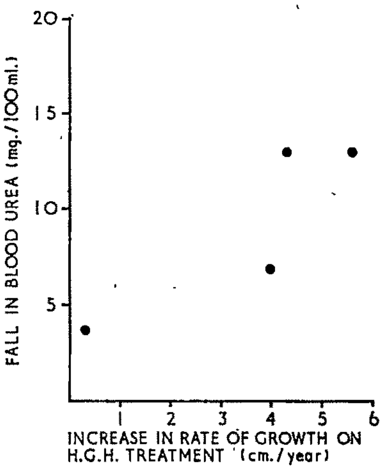

FIG. 6

FIG. 4.—Relation between changes in blood urea and urine calcium (Days 1–6). FIG. 5.—Relation between fall in blood urea (Days 1–6) and highest serum H.G.H. during insulin-tolerance test in 14 patients. FIG. 6.—Relation between fall in blood urea (Days 1–6) and growth response to H.G.H. treatment in four patients.

Discussion

The increased sensitivity of hypopituitary subjects to the metabolic effects of H.G.H. as compared with subjects without hypopituitarism which was found in the present study, agrees with the results of most other investigations (M.R.C., 1959; Daughaday and Parker, 1963; Prader *et al.*, 1964; Soyka *et al.*, 1964; Wright *et al.*, 1965; Hubble, 1966; Scott *et al.*, 1966). The metabolic response which distinguished our patients with hypopituitarism most clearly from the other subjects was their greater fall of blood urea. Nitrogen retention, as measured by the fall of urinary nitrogen, was also most marked in this hypopituitary group; however, the differences were not as great and the results overlapped more than was found with the blood urea responses, possibly because the auto-analyser blood ureas were more accurate. Even when the changes of urinary nitrogen were corrected for body weight this overlap was still present, though Prader *et al.* (1964) found a clear separation in this respect between hypopituitary subjects and controls. The hypercalciuric effect of H.G.H. was also more marked in the hypopituitary group, but again there was overlap of individual results with those of the other groups. We did, however, find a correlation between the fall of blood urea and the rise of the urinary calcium induced by H.G.H., which is contrary to the findings of others (Prader *et al.*, 1964; Wright *et al.*, 1965) and might not be expected if, as has been suggested, the hypercalciuric effect of H.G.H. is a pharmacological one and related to dosage (M.R.C., 1959).

The usefulness of an acute metabolic trial of H.G.H. in distinguishing patients with hypopituitarism from other forms of dwarfism is supported by the relation between the magnitude of the fall of blood urea and the responsiveness of circulating serum H.G.H. to hypoglycaemia. As fasting levels of serum H.G.H. may be too low to be measured, insulin-tolerance tests were performed to assess H.G.H. reserve, since hypoglycaemia is a well-recognized stimulus for growth hormone release (Roth *et al.*, 1963). Patients with serum H.G.H. levels rising above 4 mμg./ml. during insulin hypoglycaemia were found to sustain only a slight reduction of the blood urea in response to injected H.G.H., whereas the patients in whom serum H.G.H. remained undetectable throughout the insulin-tolerance test showed greater falls of blood urea. Scott *et al.* (1966) have reported similar findings. Until more data are available concerning the response of normal children to H.G.H., the significance of our results in those patients without primary pituitary disease remains difficult to assess.

Others have also found idiopathic or primordial dwarfs to be resistant to the nitrogen-retaining effect of H.G.H. (Shepard *et al.*, 1960; Lipsett *et al.*, 1961), and it seems likely that, though this group of dwarfs is probably a heterogenous one, a peripheral resistance to the action of H.G.H. might be a factor in some.

The cause of the growth defect in gonadal dysgenesis is also uncertain. Normal levels of serum H.G.H. have been found by bioassay (Forbes *et al.*, 1962) and by immunoassay (present study), and Daughaday and Parker (1963) found normal serum sulphation factor in 9 of their 12 patients. A peripheral insensitivity to the action of H.G.H. was postulated by Willemse (1962); however, Forbes *et al.* (1962) and Wright *et al.* (1965) measured the metabolic effects of H.G.H. in patients with gonadal dysgenesis and concluded that they were not subnormal. Forbes *et al.* (1962) suggested that there may be an abnormal form of circulating H.G.H. in this condition. We have tested this suggestion by measuring the serum H.G.H. from two patients by the immunoassay technique at different dilutions of serum. The slope of these assay lines was identical with that of the H.G.H. used in the standards, so that these assays failed to provide any evidence of an abnormal form of circulating H.G.H.

Overdosage with cortisone is a well-known cause of arrested growth, and two mechanisms may be involved in this. A peripheral antagonism between the actions of growth hormone and A.C.T.H. or corticosteroids has been shown both in animals (Becks *et al.*, 1944) and in man (Soyka *et al.*, 1964), and high doses of corticosteroid have been shown to suppress the release of H.G.H. from the pituitary (Hartog *et al.*, 1964a; Frantz and Rabkin, 1964). It was therefore of interest that the three patients receiving moderate doses of corticosteroids, in whom clearly measurable levels of serum H.G.H. were found, showed a smaller metabolic response to H.G.H. than that found in the hypopituitary subjects. In contrast, the patient with severe Cushing's syndrome, in whom no circulating H.G.H. could be detected, showed a response similar to that of the hypopituitary group. Hennemann *et al.* (1964) have also reported marked nitrogen retention after the administration of H.G.H. to a patient with Cushing's syndrome.

There are conflicting reports on the usefulness of measuring the metabolic response to H.G.H. in predicting the growth response to long-term H.G.H. therapy. Prader *et al.* (1964), using a dose of 2 mg./sq. m. body surface area daily (Raben preparation), found that four primordial dwarfs sustained only slight nitrogen retention with H.G.H. and failed to respond to long-term therapy, while six out of nine hypopituitary dwarfs who all sustained marked nitrogen retention showed a satisfactory acceleration of growth with long-term H.G.H. therapy. The three exceptions were patients who developed high titres of antibody to H.G.H. in the course of treatment. We have followed the growth response of only four patients, but it did appear that, in them, the degree of nitrogen retention was related to their subsequent course. Wright *et al.* (1965), using a Wilhelmi preparation 5 mg. daily, however, were unable to find any parameter in the metabolic response which was of use in predicting subsequent growth response, with the possible exception of minimal nitrogen retention, which was associated with failure of acceleration of growth with chronic H.G.H. therapy.

Summary

The acute metabolic response to injected human growth hormone (H.G.H.) has been compared in seven patients with panhypopituitarism, six cases of idiopathic dwarfism, three cases of gonadal dysgenesis, three patients dwarfed as a result of chronic corticosteroid treatment, one case of Cushing's syndrome, and three adults without pituitary disease. Change in blood urea appeared to be the most sensitive factor.

The acute metabolic response was greater in patients with hypopituitarism than in those without primary pituitary disease.

Measurements of endogenous H.G.H. in response to insulin hypoglycaemia were made in 15 subjects. The acute metabolic response to injected H.G.H. was greatest in those with no measurable serum H.G.H. in response to insulin.

The relevance of the acute metabolic response to the linear growth response was examined in four patients who received long-term treatment with H.G.H. Growth was accelerated only in the three patients showing marked nitrogen retention during the acute metabolic test.

Under the Human Pituitary Subcommittee of the Committee of Clinical Endocrinology of the M.R.C. the H.G.H. was prepared by Dr. Anne Hartree, Department of Biochemistry, University of Cambridge, and ampouled, assayed, and tested for sterility and pyrogens by Drs. D. R. Bangham, P. M. Cotes, M. P. Stack-Dunne, and G. W. Bissett, Division of Biological Standards, Medical Research Council. Growth measurements were made by Professor J. M. Tanner and Mr. R. H. Whitehouse at the Institute of Child Health, University of London.

We would like to thank the M.R.C. for a grant for technical assistance for the assay of H.G.H. We also thank the physicians who referred the patients, and the dietitians and nursing and technical staff of the metabolic unit, for all their help in these studies.

[WITH SPECIAL PLATE]

Brit. med. J., 1967, **3**, 199–202

When thrombosis of the superior mesenteric artery occurs with acute infarction of bowel the mortality rate approaches 100% in untreated cases and is over 90% in those treated surgically (Mavor *et al.*, 1963). The acute episode is preceded by prodromal symptoms of intestinal ischaemia in approximately 50% of cases (Dunphy, 1936). If these symptoms can be recognized, direct arterial surgery may avert the inevitable arterial occlusion and save life (Morris *et al.*, 1962). The provisional diagnosis of mesenteric ischaemia may be confirmed by lateral aortography of the abdominal aorta, but the principal difficulty in diagnosis is a failure to suspect that the presenting symptom pattern may be due to ischaemia of small bowel.

In most cases of chronic intestinal ischaemia due to atherosclerosis at least two of the three principal arteries to the alimentary tract must be stenosed or occluded before symptoms result (Morris *et al.*, 1962), but Morris *et al.* (1966) reported 6 out of 31 cases in which a lesion of the coeliac axis alone was the cause of symptoms. Marable *et al.* (1966) reported three cases of stenosis of the coeliac axis caused by constricting bands without superior or inferior mesenteric abnormality. This was the cause of ischaemic foregut symptoms in one of our cases.

* Consultant Surgeon, Glasgow Royal Infirmary and Peripheral Vascular Unit, Belvidere Hospital, Glasgow E.1.
† Senior Lecturer in Medicine, Glasgow Royal Infirmary, Glasgow C.4.
‡ Radiologist-in-Charge, Stobhill Hospital, Glasgow N.1.

We also report three cases of superior mesenteric occlusion and one case in which all three vessels were severely affected by atherosclerosis.

Case 1

A man aged 56 attended in October 1962 complaining of epigastric pain of one year's duration relieved by defaecation. He had occasional diarrhoea with yellow stools, and had lost 21 lb. (9.5 kg.) in weight. He had had coronary artery thrombosis in 1951 and 1954. Examination showed a thin, poorly nourished man with no specific findings, and a provisional diagnosis of malabsorption or alimentary carcinoma was made.

The principal laboratory investigations are listed in the Table. Test for faecal occult blood was negative, and barium-meal examination showed a malabsorption flocculation pattern on one film. Steatorrhoea was demonstrated, and jejunal biopsy by the peroral technique, using a Crosby capsule, showed changes in the jejunum corresponding to the group 4 lesion of Watson *et al.* (1965); that is, definitely abnormal but less severe than the changes found in adult coeliac disease.

A provisional diagnosis of mild adult coeliac disease was made, and after dismissal he improved slightly on a gluten-free diet. However, he became anaemic and was readmitted on 7 March 1963 for further investigation. One week later he had a mild cerebral attack with paresis but recovered rapidly. Faecal occult blood was present on two occasions, and radioactive chromium studies showed a daily alimentary blood loss of 5–6 ml.

At this point intestinal ischaemia or carcinoma was suspected, and at laparotomy on 1 April the small intestine was cyanotic and without detectable mesenteric pulsation. The ileocolic artery was exposed and divided, and the proximal end dilated by forcible saline injection to a calibre of about 4 mm. and anastomosed end-to-side to the right common iliac artery. On removal of the clamps mesenteric pulsation appeared and the previously cyanotic bowel became red and contractile.

His subsequent recovery was satisfactory, with relief of symptoms and gain in weight, and repeat jejunal biopsy 29 days after operation showed normal tissue. Three months after operation (Special Plate, Fig. 1) retrograde Seldinger catheterization of the right common iliac artery and injection of Urografin visualized the terminal mesenteric vessels. He thereafter remained well until December 1963, when he died from a coronary artery thrombosis.

Case 2

A man aged 54 presented on 26 February 1965 with loss of weight of two years' duration, loss of appetite for 10 months, and a tendency to constipation. He had been treated in 1961 for intermittent claudication due to bilateral femoropopliteal occlusions.

Examination confirmed the severe weight loss, the liver was just palpable, and the colon was palpable in the left iliac fossa. A provisional diagnosis of alimentary carcinoma or mesenteric ischaemia was made, and he was admitted for investigation (see Table).

Barium enema was negative, and a barium-meal examination report stated: "Irritability of the duodenal cap and coarsening of its mucosa. An ulcer crater at the base of the cap cannot be entirely excluded." Faecal occult blood test was negative.

At operation on 7 April the abdominal aorta showed severe atherosclerosis, and there was no palpable arterial pulsation throughout the alimentary tract, in the viscera supplied by the coeliac axis and superior and inferior mesenteric arteries. Revascularization was not thought feasible and the abdomen was closed. He died suddenly three days later from coronary artery thrombosis.

Case 3

A man aged 54 was investigated in February 1965. He complained of abdominal pain of three months' duration, loss of 1 stone (6.4 kg.) in weight, occasional diarrhoea, and claudication of the left thigh and calf. Barium-meal examination showed a flocculation pattern suggesting malabsorption, and florid liver palms suggested liver disease (see Table).

Lateral aortography (Special Plate, Fig. 2) showed occlusion of the superior mesenteric artery and stenosis of the common iliac arteries. At operation on 25 April 1966 there was no pulsation in the branches of the coeliac axis and superior mesenteric artery. The latter was exposed at the root of the mesentery (where it was patent), divided, and reimplanted into the aorta at a convenient level. Vigorous pulsation was restored to the mesenteric vessels and the small bowel became red and contractible.

Postoperatively he developed diarrhoea (four stools daily), which persisted for several weeks but responded to Lomotil, and he began to gain weight.

Repeat jejunal biopsy showed regression of abnormal histological changes and intestinal disaccharidase levels improved but faecal fat remained high at 10 g./day. Repeat lateral aortography showed revascularization of the small intestine.

Case 4

A man aged 51 had a coronary artery thrombosis in 1961. In 1963 he developed claudication of the left calf, and an aortogram in 1965 showed narrowing of the left common femoral artery and a left superficial femoral occlusion. At operation on 15 March 1965 a large plaque was removed from the common femoral artery and a bypass vein graft inserted from this to the popliteal artery with complete relief of claudication.

Nine months later he developed a right femoropopliteal occlusion and also complained of poor appetite and loss of weight. Barium-meal examination showed some deformity of the duodenal cap and he was put on an ulcer regimen.

In March 1966 claudication recurred in the left leg with absence of the left femoral pulse, and aortography (Special Plate, Figs. 3 and 4) showed occlusion of the left external iliac artery, the vein graft remaining patent. The inferior mesenteric artery was hypertrophied and gave origin to a large marginal artery which supplied the colon and ileum. The marginal artery was larger than in the aortogram of 1965, and a provisional diagnosis of superior mesenteric occlusion or stenosis was made.

At this time he complained of persistent postprandial pain with flatulence, and abdominal distension and early liver palms were present (see Table).

At laparotomy on 27 June there was no detectable pulsation in the stomach and small-intestinal vessels, the small intestine was cyanotic, and the inferior mesenteric and marginal arteries were hypertrophied.

After splenectomy and mobilization of the pancreas the superior mesenteric artery was found to be obliterated at its origin, owing to atherosclerosis, and pulsation in the coeliac axis was poor. The superior mesenteric artery was exposed at the root of the mesentery

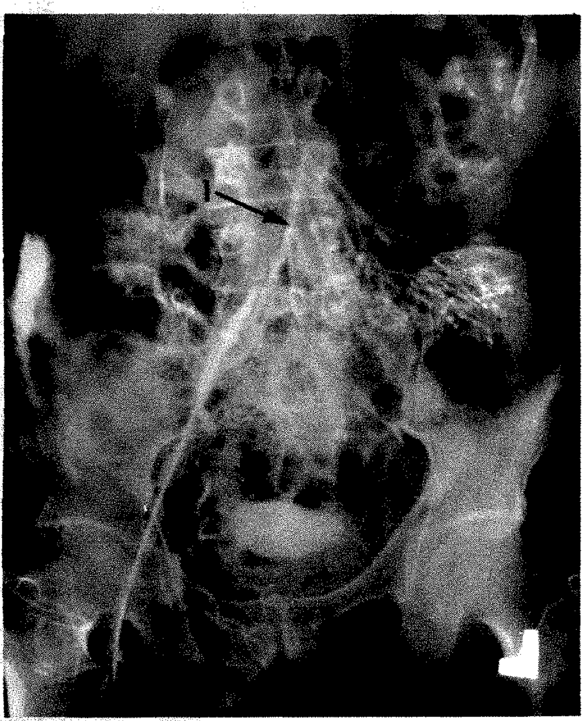

FIG. 1.—Case 1. Seldinger catheter lies in right common iliac artery and injection of dye at this site has visualized the right iliac arteries. At the same time the terminal mesenteric vessels (1) can be seen, indicating that these have filled through a patent ileocolic to common iliac anastomosis. This film was taken three months after operation.

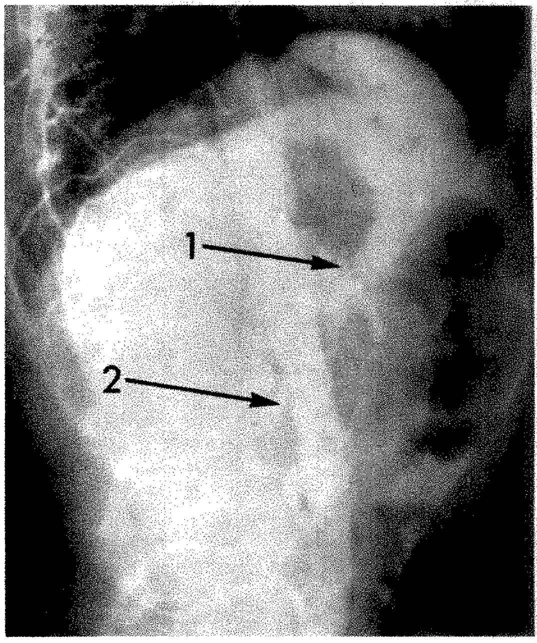

FIG. 2.—Case 3. Lateral aortogram showing dye in coeliac (1) and renal (2) arteries. Superior mesenteric artery is not visualized.

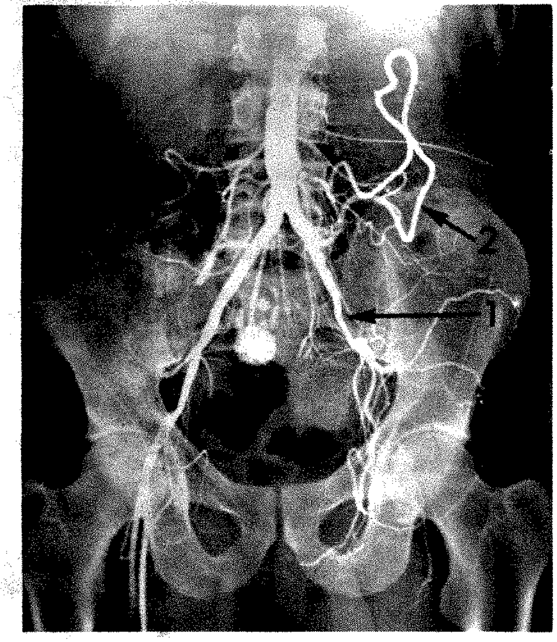

FIG. 3

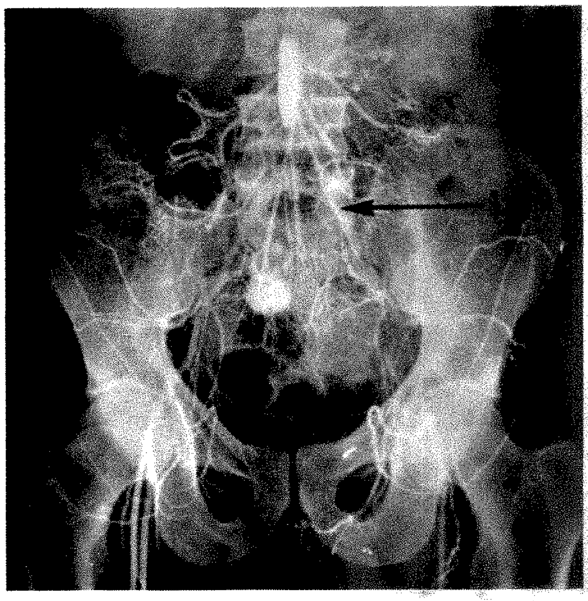

FIG. 4

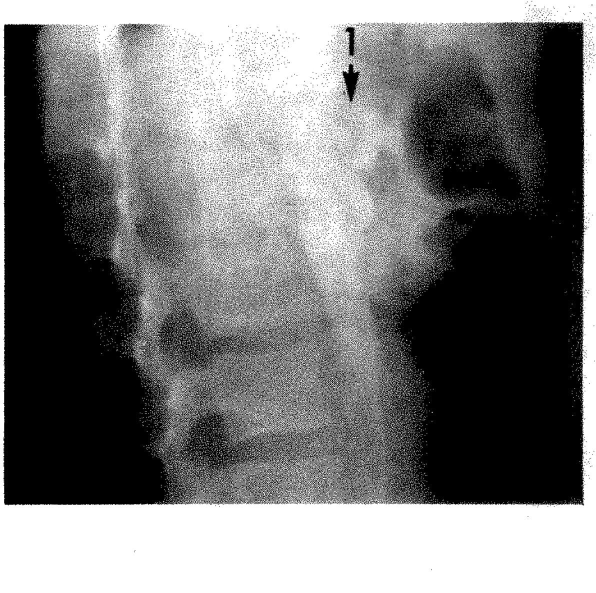

FIG. 5

FIG. 3.—Case 4. Translumbar aortogram showing occlusion of left external iliac artery (1). The inferior mesenteric artery is hypertrophied and gives origin to a large marginal artery (2).

FIG. 4.—Case 4. Late film after the injection of dye illustrated in Fig. 3. Terminal branches to small bowel (1) derived from the superior mesenteric artery can be seen. As the level of aortic injection was well below the origin of the superior mesenteric artery, the terminal mesenteric arteries must have filled from the large marginal artery and superior mesenteric occlusion can be assumed.

FIG. 5.—Case 5. Early film of lateral aortogram showing dye in proximal portions of coeliac axis and superior mesenteric artery. There is a deep notch in upper border of coeliac axis (1) without evidence of atherosclerosis of aorta.

FIG. 3.—Radiograph of skull showing osteosclerosis of base of skull as well as bones of calvarium.

and the distal normal artery reimplanted into the aorta with return of colour and pulsation in the small intestine.

Postoperatively he experienced diarrhoea for several weeks. Thereafter he was symptom-free and gained weight.

Case 5

A man aged 40 had had occasional abdominal pain for nine years, and for two and a half years had constant dull periumbilical pain with three motions daily. The pain was not related to meals but was relieved by defaecation and associated with abdominal distension. There was no loss of weight. He had previously been a heavy drinker.

Serum amylase was normal. Other investigations are listed in the Table. Lateral aortography showed narrowing of the coeliac axis (Special Plate, Fig. 5).

At operation on 31 May 1966 there was reduced pulsation in the stomach arteries and no hypertrophy of the pancreatico-duodenal anastomosis. Numerous adhesions were present round the left lobe of the liver, and the coeliac axis appeared to be compressed by the median arcuate ligament and by fibrosis around the coeliac plexus. The ligament was divided, giving normal arterial pulsation. Biopsy of the liver showed a mild inflammatory infiltration round the portal tracts with lymphocytes and occasional eosinophils.

After a smooth convalescence he continued to complain of some mild abdominal pain, but faecal fat was 1 g./day and bromsulphalein clearance 10 days after operation was normal (1.5% dye remaining at 45 minutes).

Discussion

The characteristic presentation of persistent postprandial pain in an undernourished male patient who tends to eat small meals and who may be known to have atherosclerosis constitutes a syndrome which should be readily recognizable as due to ischaemia of the midgut. Dardik *et al.* (1965) collected accounts of only 18 cases successfully treated surgically (including cases reported by Morris *et al.* in 1962), but since then Morris *et al.* (1966) have reported 31 cases treated surgically without mortality, and Rob (1965) has reported 18 cases. This relatively small number of cases, most of which were treated in large centres, suggests either that the condition is rare or that recognition of the symptom pattern is difficult. Our own experience of five cases of chronic intestinal ischaemia operated on within three years (four successfully) suggests that it is not necessarily rare.

Difficulty in diagnosis is due to lack of awareness on the part of the clinician, who fails to include intestinal ischaemia in his differential diagnosis when a patient presents with atypical abdominal pain. Fry and Kraft (1963) analysed the prodromal symptoms of 20 patients who had died from acute infarction of bowel and stated that each had experienced abdominal pain and loss of weight but that the symptom pattern was not "stereotyped."

This is certainly true, and the middle-aged patient who presents with abdominal pain and severe loss of weight may be suspected of having an alimentary carcinoma. This diagnosis was thought to be a possibility in Cases 1 and 2, but barium studies were negative. From our experience we would strongly recommend that any patient with abdominal pain and loss of weight suggestive of carcinoma, in whom barium investigations prove negative, should be suspected of having chronic intestinal ischaemia. Evidence of athersclerosis elsewhere enhances this suspicion and is an indication for lateral aortography.

Barium-meal examination showed minor abnormalities of the duodenal cap suggestive of ulcer in Cases 2 and 4, and ulcer was confirmed in Case 4 at operation. Such findings in patients with chronic intestinal ischaemia may lead to an erroneous diagnosis of duodenal ulcer and delay effective treatment. This sequence of events was observed in a patient who presented with an acute infarction of bowel, having attended elsewhere with his "ulcer" for six months.

Malabsorption is a common occurrence in visceral ischaemia. It occurred in Cases 1, 3, 4, and 5 and might have been discovered in Case 2 if the appropriate investigations had been carried out. Heard *et al.* (1963), who reported one case and reviewed 18 others from the literature, found that malabsorption was a feature in five (26%). Most of the case reports in the literature are poorly documented in this respect (Dardik *et al.*, 1965), and our experience suggests that malabsorption is commoner than the figures of Heard *et al.* indicate.

Small-bowel disease was demonstrated by steatorrhoea (Cases 1, 3, and 5), abnormal histology (Cases 1, 3, and 4), and low intestinal disaccharidase activity (Cases 3, 4, and 5). Abnormality of liver function was shown by impaired bromsulphalein excretion in Cases 3 and 4, though routine liver-function tests in these patients were normal.

Chronic ischaemia has therefore a functional effect on small intestine and liver. It may even cause abnormalities of pancreatic secretion, though we have no evidence to offer on this point. In addition to the loss of weight in these five patients, it was noteworthy that all were small, measuring from 4 ft. 11 in. to 5 ft. 5 in. (150 to 165 cm.) in height.

When mesenteric pulsation is found to be reduced or absent at operation, a variety of surgical procedures may be employed. Morris *et al.* (1966) prefer bypass Dacron graft, but employed endarterectomy in five cases. They performed single artery revascularization in 14 cases and revascularization of two arteries in 17 cases, but point out that full restoration of normal blood flow is not necessary for a good result, unlike revascularization in renal artery stenosis. Long-term survival of bypass grafts seemed good, and one had been successful for eight years.

Bypass saphenous-vein grafting (Fry and Kraft, 1963) and homografts (Mavor and Lyall, 1962; Heard *et al.*, 1963) have also proved successful.

Thromboendarterectomy is a logical procedure where the lesion is confined to the first centimetre or two of the main trunk, and this method was successfully employed in two cases by Shaw and Maynard (1958). Exposure of the origin of the coeliac axis and superior mesenteric artery from the aorta was easily achieved in Cases 4 and 5, without opening the chest, by mobilization of the splenic flexure of colon, splenectomy, mobilization of pancreas, and retraction of stomach and pancreas to the right. Occasionally stenosis may affect a longer segment of artery (Fry and Kraft, 1963—2 cases in 20) and this technique cannot be employed.

The possibility of direct arterial anastomosis between the aorta and the mesenteric vessels is illustrated by the successful result obtained by Ranger and Spence (1962) when a functioning side-to-side anastomosis was made between the aorta and ileocolic artery and by the successful result obtained in our first case by end-to-side anastomosis of the distended ileocolic artery to the right common iliac artery.

Mikkelsen (1957) advocated reimplantation of the distal portion of the superior mesenteric artery into the aorta. Experience of the satisfactory function of a reimplanted artery in cases of renal artery stenosis led to the reimplantation of the superior mesenteric artery in Cases 3 and 4. Brolin and Hansson (1964) have also reported the use of this method. The lumen of the anastomosis is not as large as that of a healthy superior mesenteric artery, but the efficiency of revascularization appears superior to that achieved by bypass grafting.

The assessment of the relative values of operative procedures to relieve chronic intestinal ischaemia will be possible only when sufficient cases become available for operation, and this requires the greater use of lateral aortography as a diagnostic procedure in suspected cases.

The prohibitive mortality of acute infarction emphasizes the necessity for early diagnosis at the stage of chronic ischaemia. Mavor and Lyall (1962) suggest that the period of prodromal symptoms is not necessarily prolonged, and in the collected series of 19 cases of Heard *et al.* (1963) the mean duration of symptoms was four to five months. This suggests that prolonged investigation and indecision are undesirable in the management of these cases.

Summary

Five cases of visceral ischaemia are presented. Successful operative and clinical results were obtained in three of the four cases of chronic intestinal ischaemia and in one case of coeliac axis stenosis.

Malabsorption was a feature of four cases. Abnormalities of faecal fat, jejunal histology, disaccharidase activity, and bromsulphalein excretion were present, and improvement or reversion to normal followed successful operation.

Chronic intestinal ischaemia should be strongly suspected in middle-aged patients with atypical abdominal pain and loss of weight, especially when alimentary carcinoma is suspected and barium studies are negative. Successful revascularization of the abdominal viscera can be achieved when the diagnosis has been proved by lateral aortography.

We wish to thank Mr. C. J. Longland for permission to include Case 2 in this report and Dr. D. Murray for the histological examination of the intestinal biopsies.

Controlled Trials of a Sulphonamide Given Weekly to Prevent Exacerbations of Chronic Bronchitis

A. PINES,* M.D., M.R.C.P.ED.

Brit. med. J., 1967, 3, 202–204

Purulent exacerbations are difficult to prevent in patients with chronic bronchitis. Trials of antibiotics administered continuously for long periods have given variable and often negative results (Elmes, 1962). Most of these studies have been in outpatients, in whom regular treatment and exact assessment are notoriously difficult (Porter, 1966). I present the results of a controlled trial of a new sulphonamide given weekly to hospital inpatients with chronic bronchitis.

Sulphormethoxine (Fanasil) is a sulphonamide with a half-life in the body of 100 to 200 hours, so that it is effective if given once weekly. In a preliminary study in this hospital it was found to have some effect in mild exacerbations of chronic bronchitis, especially when given in a 2-g. dose weekly. A weekly dose over long periods is so convenient that it seemed worth assessing the value of the drug in preventing purulent exacerbations of chronic bronchitis.

First Trial

Many of the patients in this hospital stay for long periods because of medical or social reasons, or both. Patients who suffered from chronic bronchitis were eligible for the trial if (1) they were going to stay for long periods ; (2) had a history of at least one acute exacerbation during the previous 12 months as defined by hospital admission, treatment by antibiotics, or confinement to bed at home ; and (3) had purulent sputum at the time of admission.

Plan of Trial.—In all patients the initial purulence of the sputum was cleared with courses of antibiotics. They were then divided into two groups by random selection, in a proportion of two treated to one control. Cards with treatment or control written on them were placed in sealed envelopes at random and taken in strict order of entry into the trial. As it was anticipated that many of the controls would relapse, this ratio would allow more patients to be treated. The treated patients were given sulphormethoxine 2 g. once weekly. The control patients were given symptomatic treatment only. Because sulphormethoxine is a relatively new drug in this country, a double-blind trial with a placebo as well was not thought advisable, so that a close watch could be kept for any toxicity. No antibiotics were given to patients in either group unless a purulent exacerbation occurred. The patients were admitted to the trial from January 1964 until October 1964.

Patients.—All the patients were men. Most were aged from 40 to 70 (Table I). All had had symptoms of bronchitis for at least five years. Both groups were comparable in age (Table I) and in initial distribution of quantity of sputum (Table II). The method of allocation ensured that patients entered the trial in balanced proportions during each month of the year. Those

* Ware Park Hospital, Ware, Herts.

patients who did not relapse were observed for at least four months and some for up to eight months.

Daily Observation.—A 24-hour specimen of sputum was examined for purulence and quantity. Sputum purulence was graded into three categories—mucoid, with at the most a trace of pus ; grade 1 purulence when up to 50% of the specimen was purulent ; and grade 2 purulence when over 50% was purulent. This was assessed daily by an independent observer, an experienced charge nurse who was completely unaware of whether patients were being treated or not. An exacerbation was diagnosed when the sputum became purulent, either grade 1 or grade 2, for three successive days, whether accompanied by fever or other manifestations or not. Most patients did in fact feel ill and had fever. They were then withdrawn from the trial and the exacerbation treated with an antibiotic. *Only the independent and " blind " assessment of the sputum was taken into consideration.*

The sputum was tested routinely at monthly intervals or at the time of an exacerbation for pathogenic bacteria, though these were not tested for sensitivity to sulphormethoxine. The haemoglobin, white count, and urine were tested monthly and a blood urea was taken initially. The assessments of respiratory function and additional biochemical data were regarded as unimportant in this trial and were not carried out routinely.

Results.—There were no withdrawals except where an exacerbation occurred. Of the 16 control patients exacerbations took place in 12 (75%). Of the 32 patients treated with sulphormethoxine exacerbations occurred in 11 (35%). There were no exacerbations in 4 (25%) of the 16 controls and in 21 (66%) of the 32 treated patients. The difference in the percentage of exacerbations is 40%, which is three times the standard error of 13.68%. The 95% confidence interval for the true difference is 14–68%. Sulphormethoxine seemed more successful in those patients who expectorated less than 30 ml. of sputum daily at the beginning of treatment (Table II).

Second Trial

Because of the success of sulphormethoxine and its lack of toxicity, a further trial was carried out during the winter of 1965–6. This was " double-blind " in a group of 60 patients similar to those in the first trial, again with independent assessment of the purulence of the daily 24-hour specimen of sputum. Four tablets of placebo or of sulphormethoxine (2 g.) were given weekly for a period of 10 weeks, whether relapse occurred or not.

Ten weeks' supply of tablets for each patient had been placed in a bottle by Roche Products Ltd. and numbered. The order in which either placebo or sulphormethoxine was issued was determined at random (Fisher and Yates) in a proportion of two treated to one placebo. The key to the trial was kept in a sealed envelope and not opened until both the trial and the final assessments of all patients had been completed. Though it would have been preferable for patients to continue throughout the winter in the trial, few would have stayed long enough in hospital to allow this assessment.

Patients.—Four had to be withdrawn from the trial, leaving 56 patients. Most were aged between 40 and 70 (Table III). All had had symptoms of bronchitis for at least five years (Table IV). In many patients an initial maximal peak flow reading had been obtained (Table V), and almost all showed a severe ventilatory defect. The placebo-treated patients tended to be younger, to have a shorter history of disease, to have less sputum (Table VI), and, in those tested, to have a higher range of maximal peak flow.

Results.—Three sulphormethoxine-treated patients were withdrawn (one discharged himself, cultures were positive for *Mycobacterium tuberculosis* in the second, and in the third an eosinophilia of 15% was present in the sputum). One control patient was withdrawn (eosinophilia in the sputum, 10%). In the placebo group exacerbations occurred in 13 (68%) out of 19 patients, and in the sulphormethoxine group in 14 (38%) out of 37. There were no relapses in 6 (32%) placebo-treated patients and in 23 (62%) sulphormethoxine-treated patients. The difference in the proportion of exacerbations is 30%, which is more than twice the standard error of 13.35%. The 95% confidence interval for the true difference is 3–51%. More exacerbations occurred among those patients who had over 30 ml. of sputum daily, both those treated and the controls. In those patients who had exacerbations there was a mean of 2.1 illnesses in 10 weeks among those sulphormethoxine-treated and of 1.5 among the controls. This may be related to the milder bronchitis which predominated among the latter.

Comment

When the results of both trials are combined the difference in the proportion of exacerbations is 35% and the standard error 9.603. The 95% confidence interval for the true difference lies between 16 and 54%.

Toxicity.—No toxicity or intolerance was found among any of the patients in either trial.

Bacteriology.—In both trials sputum was tested monthly as a routine. In the first trial *Haemophilus influenzae* was found at some time in 12 out of 48 patients and *Streptococcus pneumoniae* in five. In the second trial *H. influenzae* was found in eight and *Str. pneumoniae* in three. These results are too scanty to merit further analysis.

Discussion

The sulphonamides are generally held to be effective in vitro against *Str. pneumoniae* and *H. influenzae :* sulphormethoxine is equally effective in vitro (E. Bohni, personal communication, 1966). With 2 g. once weekly of sulphormethoxine plasma levels of free sulphonamide lie between 15 and 20 mg./100 ml. throughout the week, which may be comparable to that found with daily sulphadimidine by Newbould and Kilpatrick (1960). The mean half-life is 180 hours. Sulphormethoxine 1 g. weekly gives slightly lower levels (Clarke, 1964).

In previous work on the prophylaxis of chronic bronchitis sulphonamides have not been shown to be effective (Kilpatrick and Oldham, 1954; Edwards *et al.*, 1957; Francis *et al.*, 1964). However, Clarke (1964), Aguirre and Casado (1964), and Frank (1964) were impressed with sulphormethoxine in preliminary studies. With sulphormethoxine the results I have described show a definite prophylactic effect in hospital inpatients. The number of exacerbations was significantly reduced. The initiation of many relapses must often be outside the control of ordinary chemotherapy (Scadding, 1966). Nevertheless, these results are better than in most other studies utilizing antibiotics, which have usually shown no reduction in the number of acute exacerbations (Scadding, 1966). These studies with antibiotics have shown reduction in the length of the acute illness (Scadding, 1966), but this was not so with sulphormethoxine. Naturally, inpatient conditions are more sheltered; an outpatient investigation on the effect of sulphormethoxine would be necessary on a larger scale and for longer than is possible in hospital before advocating its widespread use.

Perhaps sulphormethoxine is more effective than other long-acting sulphonamides: the percentage of protein-binding is less than with sulphadimethoxine (Madribon), especially in higher levels, so that more diffusible and active sulphonamide is available. The effect of protein-binding on activity is sometimes uncertain and paradoxical (*Brit. med. J.*, 1966). The steady effect throughout the week is likely to suppress the growth of *H. influenzae* and *Str. pneumoniae* once the major proportion of the infecting population has been eradicated by the more powerful antibiotics. Sulphonamides are said to be inactivated in the presence of pus, so that it is important to clear this from the bronchi so far as is possible *before* starting chemoprophylaxis. This may explain why sulphormethoxine was not very effective in treating an actual exacerbation in the preliminary study, or in reducing the duration of each acute illness during the trials. It may be a reason why others have obtained poor results with sulphonamides alone when treating patients in whom varying amounts of pus may often have been present in the sputum at the beginning of treatment.

The tolerability of sulphormethoxine and its ease of administration once weekly are important advantages over the antibiotics used in the prophylaxis of purulent exacerbations of bronchitis. During the course of much experience with sulphormethoxine side-effects have occurred in about 2% of patients. These consisted mainly of headache, nausea, and vomiting, but very occasional cases have been described of allergic skin rashes and leucopenia, all ending in recovery. The incidence of these effects is certainly no higher than with other sulphonamides, and appears insignificant compared with the seriousness of repeated purulent exacerbations of chronic bronchitis. Theoretically the time that sulphormethoxine remains in the body may prolong sensitivity reactions. Nevertheless, experience has shown that reactions last for no longer than with short-acting sulphonamides.

Summary

Sulphormethoxine (Fanasil) is a sulphonamide which if administered once weekly gives effective levels over the whole week. Two such trials are described in hospital long-stay inpatients suffering from chronic bronchitis and in whom the initial purulence of the sputum had been cleared with antibiotics. Assessment was by " blind " independent evaluation of the daily, 24-hour sputum for purulence.

In the first trial 11 (34%) out of 32 treated patients relapsed, as did 12 (75%) out of 16 given symptomatic treatment only (95% confidence interval 14–68%). In the second trial there were relapses in 14 (38%) out of 37 treated patients and in 13 (68%) out of 19 given a placebo only (95% confidence interval 3–57%). If the results of both trials are combined the 95% confidence interval is 16–54%.

There were no side-effects.

Sulphormethoxine shows significant prophylactic benefit in patients with chronic bronchitis and should be assessed on a larger scale in outpatients.

I wish to thank the medical, nursing, and secretarial staff of Ware Park Hospital for their help; the physicians who sent me their patients; Dr. D. Linsell and Dr. P. D. Griffiths and their staff, of the Pathological Laboratory, Hertford County Hospital, for the pathological investigations; Mr. M. Hills, London School of Hygiene and Tropical Medicine, for his statistical advice; Dr. I. Lenox-Smith, Roche Products Ltd., for supplies of sulphormethoxine, for criticism, and for the unpublished information about this drug which I have quoted; and Professor J. W. Crofton, University of Edinburgh, for criticism.

A short version of this paper was given at the Fourth International Congress for Infectious Diseases, Munich, April, 1966.

ADDENDUM.—Recent but as yet unpublished experience on a very large scale during an outbreak of meningococcal meningitis, in which sulphormethoxine was used prophylactically in very high and repeated doses, has shown that the drug can occasionally produce skin reactions. These usually occurred in children, were mild, and followed a benign course. In some cases, however, they were generalized, more severe, and showed features of Lyell's syndrome.

Comparison of Methods of Expressing the Results of Augmented Histamine Tests

R. J. ABERNETHY,* F.R.C.S.ED.; R. M. ROSS,* F.R.C.S.ED.; A. G. COX,*† M.D., F.R.C.S.ED.
A. W. KAY, M.D., CH.M., F.R.C.S.; I. E. GILLESPIE,* M.D., F.R.C.S.

Brit. med. J., 1967, 3, 205–206

The augmented histamine test (Kay, 1953) has been widely used as a reliable means of measuring maximal acid secretion by the stomach. There is general agreement that the dose of histamine (0.04 mg./kg. body weight) recommended by Kay evokes a maximal or near-maximal acid response. However, the period during which the response is greatest is the subject of dispute, and workers have used the acid output in different periods to report their results. Most have used the response in the 30-minute period from 15 to 45 minutes after the histamine injection, as originally suggested by Kay. Baron (1963) showed that the maximal response did not always coincide with this period and suggested that the greatest half-hour response (the "peak half-hour") should be used whenever it occurred. Other workers have referred to the secretion during the whole 60-minute period after histamine as the maximal histamine response (Bruce *et al.*, 1959).

If the results of augmented histamine tests are expressed in different ways the conclusions may also differ. In this paper we present a detailed analysis of the effect of reporting the results in these different ways. The data are taken from acid tests in a consecutive series of 100 patients with duodenal ulcer studied before and after vagotomy with a simple drainage procedure.

Materials and Methods

Each patient had an augmented histamine test and a "medical vagotomy" test (Gillespie and Kay, 1961) before operation, and an augmented histamine test and an insulin test approximately 8 to 10 days after operation. Each test was carried out after a 12-hour fast. Before operation a radio-opaque nasogastric tube was passed under fluoroscopic control. In the postoperative tests use was made of a gastrostomy tube placed in the stomach at operation. Gastric secretions were collected by continuous suction by electric pump, with occasional interruption to ensure patency.

In the augmented histamine test four basal specimens were aspirated at 15-minute intervals after removal of the fasting juice. Mepyramine maleate, 50 mg., was injected intramuscularly, and 30 minutes later histamine acid phosphate, 0.04 mg./kg. of body weight, was given by subcutaneous injection. Thereafter 15-minute aspirates were collected for one hour.

In the medical vagotomy test a combination of hexamethonium bromide, 50 mg., and atropine sulphate, 0.325 mg., was given as a single deep intramuscular injection one and a half hours before the injection of histamine. The details of antihistamine and histamine dosage and timing were otherwise the same as in the augmented histamine test.

In the insulin test 20 units of soluble insulin was given intravenously after collection of two 15-minute basal specimens. Blood sugar concentration fell to below 35 mg./100 ml. in all cases. Fifteen-minute aspirates were collected for two hours after the insulin injection.

The volume of each 15-minute specimen was measured. After filtration acid concentration was measured by titration against 0.1 normal sodium hydroxide with phenol red as indicator (end-point *p*H 6.8–8.4). Acid outputs were obtained by multiplication of volume and concentration values and expressed as mEq.

The response to the insulin test was classified as positive if the criteria of Hollander (1951) were satisfied at any time within the two hours of collection of specimens after the insulin injection. A positive response was denoted by an increase in acid concentration of more than 20 mEq/l. over basal concentration or by an increase in concentration of more than 10 mEq/l. in the presence of basal anacidity.

Analysis of Results

For the purposes of this analysis the results of all augmented histamine tests were expressed in three different ways: (1) "mid-half-hour," acid output in the 15- to 45-minute period after histamine; (2) "peak half-hour," acid output in the 30-minute period giving the greatest response after histamine; and (3) "whole hour," acid output in the 60 minutes after histamine. Each of these methods of reporting the results was compared with each of the others by calculating the correlation coefficient between each possible pair.

Table I shows the exceptionally high degree of correlation between each pair of measurements in (*a*) the preoperative augmented histamine response, (*b*) the medical vagotomy modification, and (*c*) the postoperative augmented histamine response. Similarly, as shown in Table II, there was good correlation between the three pairs of measurements when the effects of medical and surgical vagotomy were expressed as percentage reductions of the preoperative augmented histamine response. These correlations were not so close to unity, because each point represents the results of four tests. Despite this, all correlation coefficients were statistically significant.

Within the series of 100 patients there were subgroups which differed significantly one from the other with regard to

TABLE I.—*Correlation Coefficients Between Results of the Augmented Histamine Response Expressed in Three Different Ways* (100 *Cases*)

	Peak Half-hour v. Mid-half-hour	Mid-half-hour v. One Hour	One Hour v. Peak Half-hour
Preoperative augmented histamine response	0·925	0·909	0·942
Medical vagotomy response ..	0 909	0·949	0·961
Postoperative augmented histamine response	0·927	0·948	0·977

All correlation coefficients are statistically significant (P < 0·001).

TABLE II.—*Correlation Coefficients Between Reduction of Augmented Histamine Response by Medical and Surgical Vagotomy Expressing the Results in Three Ways*

Percentage Reduction of Augmented Histamine Test by:	Peak Half-hour v. Mid-half-hour	Mid-half-hour v. One Hour	One Hour v. Peak Half-hour
Medical vagotomy	87 cases 0·752	89 cases 0·777	89 cases 0·820
Surgical vagotomy	99 cases 0·881	98 cases 0·885	98 cases 0·948

All correlation coefficients are statistically significant (P < 0·001).

augmented histamine response. A notable example was the difference between the two sexes, the males secreting more acid than the females. It was of interest to see whether this difference was quantitatively the same with each of the different methods of expressing the augmented histamine response. Table III shows that the male/female ratios for all three methods were virtually identical, as were the Student's *t* test values for each.

TABLE III.—*Comparison of Differences Between Male and Female Preoperative Augmented Histamine Responses with the Three Methods of Expression (Standard Deviations in Parentheses)*

	Mean Values of Test		Ratio of Male/Female (Mean Values)	*t*	P
	Males (83)	Females (17)			
Mid-half-hour secretion	19·9 (±8·0)	13·3 (±5·3)	1·50	3·284	<0·01
Peak half-hour secretion	22·0 (±8·0)	15·2 (±6·2)	1·45	3·319	<0·01
One hour secretion ..	33·8 (±13·8)	22·8 (±10·3)	1·48	3·123	<0·01

Finally, the effect of taking the three different estimates of augmented histamine response was observed in comparing two subgroups whose responses differed by a much smaller amount. These were the group with a negative response to insulin and the group with a small positive response occurring late in the two-hour collection period after the insulin injection. Though the classification of this late type of insulin response was made on an arbitrary basis, it had previously been found that the reduction in augmented histamine response due to vagotomy in patients comprising this subgroup was greater than the reduction in those with large and early positive insulin responses, and only slightly less than the reduction seen in those with completely negative insulin responses (Ross and Kay, 1964). Table IV shows that the relation between the two insulin groups is virtually the same regardless of the method used to express the augmented histamine responses.

TABLE IV.—*Comparison of Percentage Reduction in Augmented Histamine Response in Patients with a Negative Insulin Test, and Those with a "Late Positive" Insulin Test After Vagotomy and Drainage (Standard Deviations in Parentheses)*

	Percentage Reduction of Augmented Histamine Response		Ratio of % Reductions: Negative/Positive	*t*	P
	Insulin Negative (69 cases)	Insulin "Late Positive" (27 cases)			
Mid-half-hour output	75% (±18·3)	56% (±19·3)	1·34	4·551	<0·01
Peak half-hour output	69% (±17·5)	54% (±20·8)	1·28	3·579	<0·01
One hour output..	73% (±18·9)	58% (±20·4)	1·26	3·377	<0·01

Conclusions and Summary

It can be seen from Tables I and II that there was a highly significant degree of correlation between the three methods of expressing the results. Tables III and IV show that when differences exist between the results of subgroups of patients within the series these differences are of the same magnitude, regardless of the way in which the results are expressed.

We therefore conclude that variations in the method of expressing the results of the augmented histamine test are unlikely to alter the conclusions derived from a particular series of such tests. It is likely, therefore, that conclusions in studies using different ways of expressing the test responses can be directly related one with another.

Late Changes in Peripheral Blood after Thorotrast Administration

A. O. LANGLANDS,* M.B., CH.B., B.SC., D.M.R.T., F.F.R.; E. R. D. WILLIAMSON,* M.B., B.CH.

Brit. med. J., 1967, 3, 206–208

From its introduction in 1930 a stabilized colloidal suspension of ^{232}thorium dioxide (Thorotrast) was extensively used either to outline body cavities, such as the renal pelvis or the paranasal sinuses after direct injection, or as a contrast medium in angiography, and, after deposition, for visualization of the liver and spleen. Its use was largely discontinued in 1947 after the report of MacMahon *et al.* (1947) on the first malignancy due to Thorotrast. Horta *et al.* (1965) reported a follow-up study of some 1,100 persons who had received Thorotrast. In addition to malignancies arising at sites of Thorotrast deposition 16 deaths out of a total of 699 were due to leukaemia, aplastic anaemia, or purpura.

We have recently undertaken a study of patients who had received intra-arterial Thorotrast, in an attempt to obtain information on the morbidity and haematological and cytogenetic changes due to Thorotrast. The purpose of this communication is to report the findings on examination of peripheral blood from these patients.

Material and Methods

Between 1930 and 1947, during investigation in the department of surgical neurology, Edinburgh, 137 patients received intra-arterial Thorotrast. In 1966 there were 37 survivors still residing in Edinburgh or near by. A venous blood sample was obtained from 35, comprising 18 men and 17 women. With one exception all had received Thorotrast before 1947.

The details of Thorotrast administration in these patients are summarized in Table I.

Packed cell volumes were determined according to the method described by Dacie and Lewis (1963) ; haemoglobin was esti-

TABLE I

	Age (years)		Dose Thorotrast (ml.)		Latent Period (years)	
	Range	Mean	Range	Mean	Range	Mean
18 men	37–71	52·4	12–50	26·2*	19–30	22·7
17 women	33–78	56·6	10–90	24·9	11–31	24·2

* Based on 13 cases. The dose was unrecorded in five.

mated photoelectrically as oxyhaemoglobin; white blood cells and platelets were counted, after bulk dilution, in a new Neubauer counting-chamber. Films made from fresh blood were air-dried, fixed in methanol for 10 minutes, and stained by May–Grunwald–Giemsa.

Absolute values for polymorphonuclear leucocytes, lymphocytes, monocytes, and eosinophils were calculated using the total white cell count and a differential white cell count based on 200 cells.

Results

In all 35 patients the packed cell volume, haemoglobin level, white cell count, and platelet count were within the normal range. A few patients showed a relative lymphocytosis, but the mean values for the differential white cell count did not differ significantly from the normal values given by Dacie and Lewis (1963). The mean values are shown in Table II.

TABLE II

	P.C.V.		Hb (g./100 ml.)		W.B.C. (× 10³/cu. mm.)		Platelets (× 10³/cu. mm.)		Neutrophils		Lymphocytes		Monocytes		Eosinophils

The most striking feature on examination of peripheral blood films was a disturbance of red cell morphology. There was a varying degree of anisocytosis, with occasional well-filled macrocytes, and, in addition, numerous burr cells and occasional target cells and stipple cells were present. Giant platelets were a common finding. Howell–Jolly bodies were present in 34 out of 35 films, the exception being that of a woman of 55 who, 23 years previously, had received 40 ml. of Thorotrast during right carotid angiography. On examination of her neck a hard mass was found at the site of injection. *X*-ray films showed this to be a dense aggregation of Thorotrast. Virtually no Thorotrast was visible in the spleen on abdominal *x*-ray examination.

In each of eight patients 1,000 red cells were counted, the percentages of abnormal cells being recorded in Table III. Fig. 1 shows a field from a peripheral blood film which illustrates these findings.

TABLE III

Case No.	Sex and Age	Thorotrast (ml.)	Latent Period (years)	Burr Cells	Target Cells	Stipple Cells	H.J. Bodies	Giant Platelets
				Per 100 Red Blood Cells				
1	F 61	18	11	7	5	1	0·8	+
2	F 42	45	30	7	1	1	0·9	+
3	F 51	90	21	2	1	1	0·9	+
4	F 40	20	23	7	1	1	0·5	+
5	M 60	26	24	12	2	1	2·6	+
6	M 54	38	25	8	2	1	1·5	+
7	M 55	36	20	6	2	1	0·5	+
8	M 56	14	25	2	1	1	0·5	+

Discussion

The presence of Howell–Jolly bodies in erythrocytes is classically associated with removal of the spleen but also occurs in congenital absence of the spleen (Bush and Ainger, 1955), in the splenic atrophy which is occasionally associated with steatorrhoea (Boveri, 1942; Fraser *et al.*, 1966), and in a variety of dyshaemopoietic states such as megaloblastic anaemia and leukaemia (de Gruchy, 1964). Nevertheless, the finding of Howell–Jolly bodies in erythrocytes is a rare event in the absence of a history of splenectomy. Boveri reviewed all the haematological reports for a five-year period at Guy's Hospital and could find only seven cases, in addition to the two he described in detail, in which Howell–Jolly bodies were reported in non-splenectomized patients. Of these, three were cases of pernicious anaemia with haemoglobin levels in the region of 60–70%, and one was a case of carcinomatosis with a haemoglobin level of 20%.

The finding of Howell–Jolly bodies in erythrocytes in 34 out of our 35 cases is therefore all the more striking in view of the otherwise normal haematological findings in these patients (Table II).

Howell–Jolly bodies have been demonstrated in the later erythroblasts in cases of vitamin-B_{12} or folic-acid deficiency (Hutchison and Ferguson-Smith, 1959; Dawson and Bury, 1961; Fraser *et al.*, 1966). The last-mentioned authors, in contrast to Hutchison and Ferguson-Smith, also demonstrated Howell–Jolly bodies in erythroblasts after splenectomy. We have been able to examine only two marrow preparations from Thorotrast patients, both of whom had Howell–Jolly bodies in erythrocytes. In neither case were Howell–Jolly bodies seen in marrow erythroblasts.

The presence of burr cells is a less reliable index of a disturbance of splenic function and occurs in other diverse conditions such as glomerulonephritis and gastric carcinoma (Schwartz and Motto, 1949). In microangiopathic haemolytic anaemia

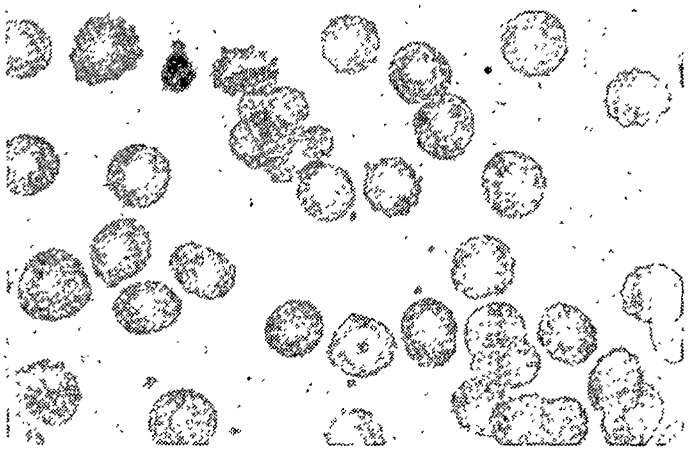

FIG. 1.—Peripheral blood. (×1,110.)

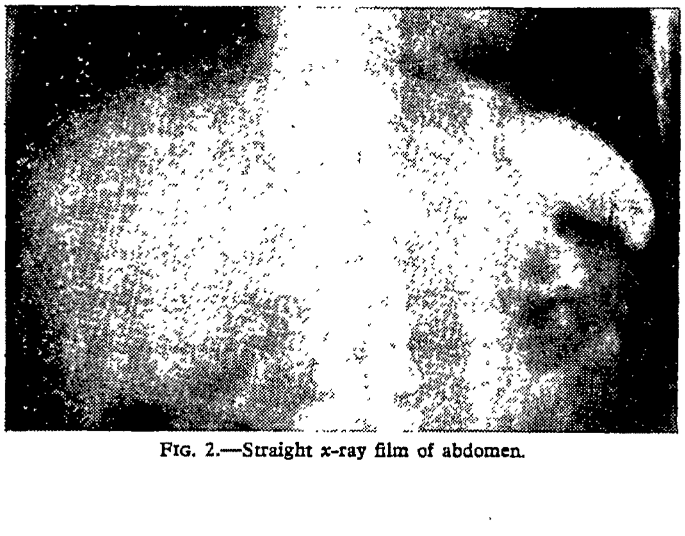

FIG. 2.—Straight *x*-ray film of abdomen.

direct contact between erythrocytes and damaged blood vessels may be a factor in the production of burr cells (Brain *et al.*, 1962). Burr cells were present in all cases that we examined.

The peripheral blood film in our patients is therefore in many ways similar to that seen after removal of the spleen. In two patients the level of Howell–Jolly bodies was greater than that said to occur after splenectomy (0.3% of erythrocytes) and was closer to the higher values (3.9–5.3% of erythrocytes) which Fraser *et al.* reported in three cases of splenic atrophy associated with steatorrhoea.

The significance of these findings, we believe, is twofold. Firstly, the sequelae of Thorotrast characteristically occur after a long latent period—of the order of 20 years or more—and most patients are unaware that the injection has been made. In the absence of a history of splenectomy previous Thorotrast administration may be suspected when the peripheral blood film shows the changes usually associated with removal of the spleen. This is particularly so when haematological examination is otherwise normal.

Secondly, these changes may be indicative of a progressive loss of splenic function in patients exposed to Thorotrast. After intravascular injection the particles of thorium are phagocytosed by reticuloendothelial cells and are deposited mainly in the spleen and liver, and to a lesser extent in the bone marrow. Fig. 2 shows the appearances of heavy deposits of thorium in the spleen of a 33-year-old woman who at the age of 13 had 20 ml. of Thorotrast injected into the left carotid artery.

Attempts to estimate dosage to the spleen from the radioactive material deposited there are for technical reasons extremely difficult, but the dosage has been calculated by Rundo (1955) to be in the region of 1,100–1,300 rep[1] of α-rays and 130–150 rep of β-rays 20 years after an injection of 20 ml. of Thorotrast. As a result of this irradiation, and the interstitial fibrosis which follows the deposition of thorium in tissues, it is not unreasonable to postulate that over the years there will be a progressive loss of splenic function in these patients, and that this will underlie the peripheral blood changes we have described. The careful study and follow-up of such cases may therefore provide useful information regarding the effects of the loss of splenic function and its possible role in some of the sequelae of Thorotrast administration.

Summary

Thirty-five persons who had received intra-arterial Thorotrast 11 or more years previously were examined. A consistent finding in films of peripheral blood was a disturbance of red cell morphology and the presence of Howell–Jolly bodies. In the absence of splenectomy, and when haematological examination is otherwise normal, such findings are extremely rare. It is thought likely that a progressive loss of splenic function has occurred in these patients as a result of irradiation and that this has caused the peripheral blood changes which we have described. More refined studies of splenic function in such patients are indicated.

We are grateful to Professor Norman Dott, Professor John Gillingham, Dr. Kate Herman, and Mr. Jeffrey Maccabe for access to their case records and permission to study patients under their care. Dr. J. T. Boyd, of the M.R.C. Radiation Registry, kindly provided follow-up information. We are also grateful to Miss Zoe Fotheringham for help in tracing patients.

Brit. med. J., 1967, 3, 208–212

The association between thrombophlebitis and carcinoma has become well recognized since it was first described by Trousseau in 1865. The following cases suggest that there may be a similar association between digital ischaemia and malignant disease. Digital ischaemia as an early or presenting feature of malignant disease has not been described before.

Case 1

A woman aged 59 was well until December 1958, when severe pain developed in the left side of her face after the extraction of a left upper wisdom tooth. The left nostril was obstructed and discharged pus. After antral washouts these symptoms were to some extent relieved.

In February 1959, after taking a hot bath, she noticed that the index and middle fingers of the left hand had become numb and white. The left middle finger was painful, and there was an area of discoloration at its tip, which later became black. A persistent pain, severe enough to prevent sleep, developed in the finger.

A year before this episode her right foot had become cold and white, and she had felt a pain in her right calf on walking uphill. Tolazoline hydrochloride was given by her doctor, and these symptoms soon disappeared. She habitually smoked 20 cigarettes a day. In 1949 she had had a gastroenterostomy for duodenal ulcer.

The severe pain led to her admission to hospital. On examination her general appearance was of good health, but there was a slight swelling of the left side of her face. The terminal phalanx of the left middle finger was black and dry. Adjacent to this was an area of painful erythema. The remainder of the finger was swollen and fixed in the extended position. There was a small area of discoloration on the pulp of the left index finger (see Fig. 1). Both fingers were colder than the other fingers of the left hand. Her blood pressure was 150/90, and the peripheral pulses, including the brachials and radials, were present and normal. There was no evidence of heart disease. Clinical examination was in all other respects normal.

Investigations.—Hb 67%. W.B.C. 10,200/cu. mm., normal differential count. No L.E. cells. E.S.R. 50 mm./hr. Electro-

---

* University College Hospital, London W.C.1.
† Present address: Aberdeen Royal Infirmary.

phoretic strip normal. Chest *x*-ray normal. *X*-ray examination of the thoracic inlet showed disc degeneration in the lower cervical spine but no cervical rib. E.C.G. normal. Arteriography revealed normally patent left subclavian and brachial arteries. A reactive hyperaemia test resulted in flushing of the whole of the left hand with the exception of the tips of the index and ring fingers and the middle finger distal to the proximal phalanx.

The condition of the left middle finger failed to improve and amputation was performed. Two weeks later left cervical sympathectomy was carried out. At operation two small soft plaques of atheroma were palpable in the subclavian artery but were not causing obstruction. After this operation she again developed pain in the left side of her face. The left nostril was found to be occluded by a friable mass, which on biopsy proved to be anaplastic carcinoma arising from the maxillary antrum.

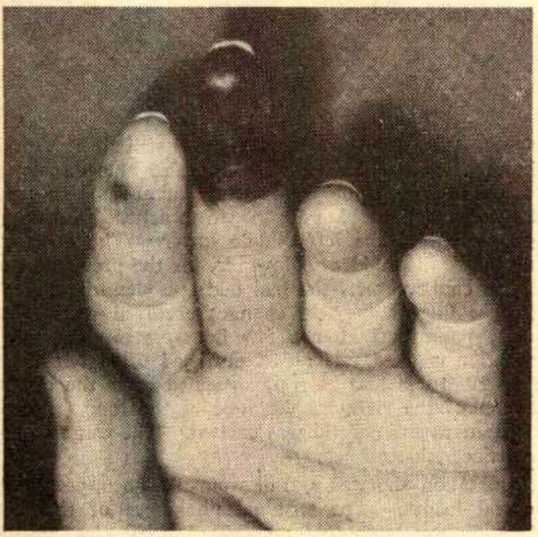

FIG. 1.—Case 1. Necrosis involving the terminal phalanges of the left index and middle fingers.

A course of palliative radiotherapy was soon discontinued, as the growth was not responding and was beginning to invade the orbit. She was discharged home on sedatives and analgesics, and died in June 1959.

Case 2

A woman aged 54 complained of coldness, numbness, and pain in the fingers of three months' duration. She first noticed her symptoms after she had been shopping on a cold winter morning. The distal two phalanges of the right middle finger had become cold, pale, and numb. These changes passed off with massage, but a few days later the tips of the fingers of both hands became painful and black (see Fig. 2). There were no changes in the feet and there was no history of sensitivity to cold or ingestion of drugs.

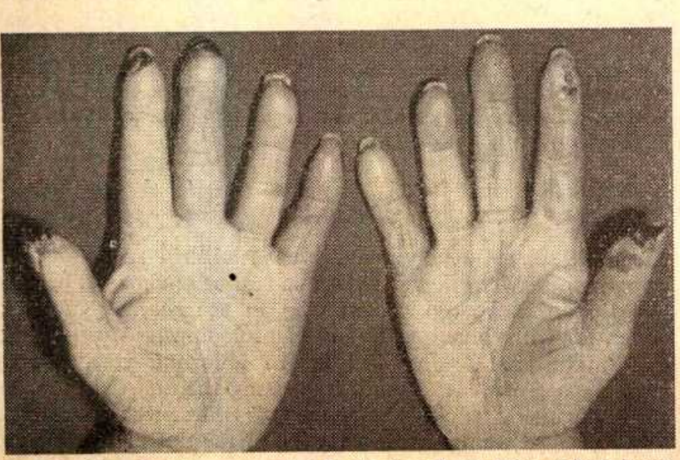

FIG. 2.—Case 2. Necrotic patches at the tips of the digits of both hands.

After admission to hospital for investigation she developed a low-grade fever for which no cause was found. She was then referred to University College Hospital, and while awaiting admission developed a right pleuritic pain and slight dyspnoea. She had had appendicectomy and cholecystectomy seven years previously and an attack of jaundice five years later. Otherwise she had been well. She smoked 10 cigarettes a day.

On examination she looked well. Her fingers were dusky and the skin was thickened. Black necrotic areas were present at the tips of all digits except the left little finger. There were areas of erythema and cyanosis and the fingers felt cold. Radial and ulnar pulses were absent in the right arm but present in the left. Leg pulses were present with the exception of the dorsalis pedis. Fundi were grade 0. B.P. was 140/90. There were no other cardiovascular abnormalities, and clinical findings, including pelvic examination, were otherwise negative.

Investigations.—Hb 92%. E.S.R. 72 mm./hr. Red cells normal. W.B.C. 6,600, with normal differential count. Blood urea 26 mg./100 ml. Plasma albumin 3.7 g., globulin 4.8 g./100 ml. Electrophoretic strip showed moderate increase of gammaglobulin and small increase of alpha-2 globulin. Plasma cholesterol 170 mg./100 ml. No cryoglobulins or excess macroglobulins. Serum cold agglutinins negative. No L.E. cells. Wassermann reaction and Kahn and Reiter protein complement-fixation tests negative. Catheter specimen of urine: red cells 3–5 per one-sixth field; pus cells 1–3 per one-sixth field; otherwise no abnormality. Chest *x*-ray examination: right pleural effusion, no cervical rib. Pleural fluid contained lymphocytes and red cells, but no malignant cells. Culture and guinea-pig inoculation negative. Pleural biopsy and bronchoscopy negative. Blood culture negative. Stool occult blood negative. Barium meal and follow-through normal. E.C.G. normal. A reactive hyperaemia test showed slight delay in the vasodilatation of the digital arteries.

While under investigation she developed a pleural effusion and recurrent fever. After four weeks her condition began to improve. Her right wrist pulses returned and the gangrenous lesions healed. Her pyrexia ceased, though she continued to lose weight. The cause of her condition remained obscure.

In view of her improvement she was discharged home. Within a few weeks she was readmitted in a confused and drowsy state and died shortly afterwards. At postmortem examination the upper two-thirds of the right kidney were replaced by a large hypernephroma. There were multiple brain secondaries but her lungs were clear. A secondary in the wall of the atrial septum and deposits in the right ovary were present.

Case 3

A woman aged 45 had undergone excision of the rectum for carcinoma in 1954. She was then well until September 1964, when a vaginal discharge occurred. Three months later she had an attack in which her fingers became dead-white and later blue. Since that time, on exposure to cold her fingers turned white, then blue, and then became red and tingled. Later her fingers remained persistently discoloured and painful, the symptoms becoming more severe during the course of each day, so that she was unable to use her finger-tips, though gangrene did not appear.

She had always tended to have cold fingers and had suffered from chilblains. Her general health was good. There was no family history of "Raynaud's disease," and she was a non-smoker.

On examination she looked fit and was not anaemic. Her fingers were blue and there were splinter haemorrhages under the nail edges. The peripheral pulses, including radials and ulnars, were palpable and normal. Her pulse was regular, B.P. 180/90, and there was no other cardiovascular abnormality. There was an irregular mass in the left hypochondrium and, per vaginam, the uterus felt bulky and fixed.

Investigations.—Hb 75%. W.B.C. 8,000, normal differential count. E.S.R. 43 mm./hr. Electrophoretic strip showed decrease in albumin and in alpha-1 globulins, but no evidence of cryoglobulins. Chest *x*-ray normal. *X*-ray examination of thoracic inlet showed no abnormality. A reactive hyperaemia test showed normal flushing of the upper limbs with the exception of the distal halves of the fingers of both hands.

Laparotomy was performed. There was a large mobile carcinoma of the splenic flexure. The uterus was bulky and there was a large cystic tumour of the left ovary. There were secondary deposits in the omentum but not in the liver or peritoneum. Partial colectomy and a modified Wertheim hysterectomy were performed. Histology showed a primary carcinoma of the colon with metastases in lymph nodes, omentum, and ovary. The uterine tumour proved to be a primary carcinoma of the body.

She made a good recovery and remained well for some weeks, though the ischaemic changes in her fingers persisted. She was readmitted in July 1965 with carcinomatosis and died three weeks later.

Case 4

A woman aged 45 had been well until May 1957, when in the course of a brief illness, during which she suffered from a sore throat, diarrhoea, and generalized aches, she began to develop symptoms in her hands. Her fingers became numb and felt cold. Her original symptoms resolved but her fingers became painful and blue and then black at their tips. The fingers were slightly swollen and the skin began to flake off. She had had no serious illness and had not been unduly sensitive to cold. She was a non-smoker and there was no family history of "Raynaud's disease."

On examination she looked fit. The tips of the index and middle fingers of both hands were blue, cold, and tender. The changes originally noticed in the other fingers had resolved. All peripheral pulses, including the digitals and radials, were normally palpable. Her pulse was regular, the B.P. 200/125, and there was a soft apical systolic murmur. There was no other abnormality on clinical examination.

Investigations.—Hb 92%. W.B.C. 7,800, normal differential count. E.S.R. 12 mm./hr. Catheter specimen of urine normal. Cold agglutinins negative. No cryoglobulins detected. Electrophoretic strip showed small increase in gammaglobulin. Chest *x*-ray normal. E.C.G. normal.

Her symptoms resolved spontaneously and the cause remained obscure. She was readmitted in October 1957 complaining of a painful swelling in the lower abdomen. A tender mass arising from the pelvis was present. At laparotomy she was found to have a malignant left ovarian cyst. There were secondary deposits in the omentum, aortic glands, and liver, and the tumour was irremovable. Histology was that of a poorly differentiated adenopapillary carcinoma of the ovary. A course of palliative radiotherapy was given. She subsequently developed ascites and died shortly afterwards.

Case 5

A woman of 58 first attended hospital in June 1965, when she complained of attacks of pain, numbness, and pallor in her fingers which had started six months previously. These changes were first noticed in both middle fingers, and the attacks lasted about half an hour. Each attack would end with a tingling sensation in the fingers and a return to their normal colour without intermediate rubor or cyanosis. Gradually all the fingers distal to the proximal interphalangeal joints became affected, but the thumbs were never involved. The attacks, which became increasingly frequent, were usually precipitated by exposure to cold.

Shortly after the onset of these symptoms her sleep began to be disturbed by paraesthesiae over the flexor surfaces of her forearms and wrists and the lateral halves of her palms. Her fingers were not usually affected. These attacks were quite distinct from those brought about by exposure to cold. Her nocturnal symptoms were attributed to bilateral carpal tunnel syndrome. The diagnosis was supported by the finding of grossly abnormal conduction times in the median nerves. There was some response to hydrocortisone injections and splintage, but her digital symptoms continued.

In October 1965 she was admitted to hospital with dyspnoea, abdominal pain, nausea, and diarrhoea of three weeks' duration. She felt rather unwell with a vague abdominal discomfort for about one year. There was no significant family history and she did not smoke.

On examination she looked ill and was found to have a left pleural effusion and ascites. Her hands showed no abnormality and all peripheral pulses were present, including both brachials and radials. Her B.P. was 120/70, the pulse regular, and an apical systolic murmur was present. There was no abnormality in the C.N.S., and clinical examination was otherwise negative.

Investigations.—Hb 100%. E.S.R. 65 mm./hr. W.B.C. 8,000, normal differential count. Midstream specimen of urine normal. Sputum showed no malignant cells. No L.E. cells found. Serum albumin 2.9 g., globulin 3.5 g./100 ml. Empirical liver-function tests normal. No cryoglobulins found. *X*-ray examination showed left pleural effusion and disc degeneration of cervical spine only. Barium-meal examination showed pyloric antrum displaced forwards, suggesting a retroperitoneal mass. Barium enema showed sigmoid diverticular disease. Both pleural and ascitic fluids contained malignant cells suggestive of adenocarcinoma. A reactive hyperaemia test showed normal vasodilatation as far as the proximal interphalangeal joints.

The ascites and pleural effusion were tapped and the fluids replaced by radioactive gold. Some delay in the reaccumulation of fluid was achieved by this means and she was discharged home, where she died in February 1966. Her primary neoplasm was presumed to be pancreatic or ovarian.

Case 6

A woman aged 42 was admitted to hospital in April 1953 complaining of persistent pain, tingling, and blue discoloration of some of her fingers. One week before admission the tip of the left index finger became blue and began to ache. Next day similar changes occurred in the left middle finger. The onset of these symptoms was quite sudden. However, for the previous two years, especially in cold weather, she had had episodes of numbness and pallor in her fingers. These changes occurred without warning and usually passed off after a few hours, sometimes assisted by the application of heat. Her feet also had often felt numb. In September 1950 she had been investigated after the discovery of consolidation of the right middle lobe of the lung. Also at this time a tumour of the parotid was excised. The cause of her chest lesion remained obscure.

On examination she was a frail woman who appeared to be in poor general health. The terminal phalanges of the left index and middle fingers were cold and blue, with a loss of sensation in the involved areas. The radial, ulnar, and digital arteries were all palpable. There was an enlarged gland in the right supraclavicular region and a varicose ulcer on the left leg. The foot pulses were palpable and there was no other cardiovascular abnormality. The signs of consolidation were still present in the right chest and the right kidney was palpable. The affected fingers made a slow recovery to normal colour with the exception of the top of the left middle finger, which became gangrenous. In hospital it was noticed that her other fingers had become transiently cyanosed.

Investigations.—Hb 78%. W.B.C. 12,000, normal differential count. E.S.R. 65 mm./hr. Sputum and gastric washings were negative for malignant cells and acid-fast bacilli.

The supraclavicular gland was excised, and proved to be involved by Hodgkin's disease. Review of the parotid tumour suggested that this also was Hodgkin's disease. She was given a course of radiotherapy to the neck region and mediastinum.

She was readmitted in July 1953 in an emaciated condition with polyarthritis and multiple enlarged glands. On this occasion her serum was found to contain cryoglobulins. Other investigations: W.R. and Kahn test negative; bone marrow normal; plasma protein showed marked rise in alpha-2 globulin and slight reduction in albumin; chest *x*-ray examination revealed persistent right middle lobe collapse.

Her condition did not improve despite treatment with A.C.T.H., cortisone, and nitrogen mustard. She died in November 1954. At post-mortem examination she was found to have widespread Hodgkin's involvement of hilar and aortic lymph nodes and glands in the porta hepatis.

Discussion

A few isolated reports have been published suggesting an association between digital ischaemia and carcinoma. The first was that of a young woman who in the summer of 1866 presented with blue, cold, and painful fingers (Fagge and Pye-Smith, 1891). She died in the following year, and at necropsy a growth was found infiltrating the first dorsal nerve and sympathetic trunk. O'Connor (1884) described the case of a middle-aged woman with gangrene of the tips of her fingers. She subsequently developed a mass of supraclavicular glands on the left side which were thought to be metastases from a carcinoma of the breast. Before the onset of her digital symptoms a lump had been removed from the left breast. Pasteur and Price-Jones (1901) described the case of a man of 61 who in the terminal stages of carcinoma of the stomach developed cold blue extremities said to be like "Raynaud's disease." Hamilton (1920) saw a man of 54 with advanced carcinoma of the oesophagus who developed typical "Raynaud's disease." Bennett and Poulton (1928) reported the case of a man of 61 who developed "Raynaud's disease" the previous summer. He died during the performance of a cervical sympathectomy for severe pain, and necropsy revealed the presence of an occult carcinoma of the stomach. In these reports it is not made clear whether the digital ischaemia was persistent or occurred in attacks.

No further reports were published until Domz and Chapman (1961) described the case of a woman of 56 with digital ischaemia and gangrene of the distal third of the left index finger. She proved to have myelofibrosis, an adenocarcinoma of the lower lobe of the right lung, and cryoglobulinaemia. After resection of the tumour her digital symptoms resolved within a week and separation of the necrotic finger-tip followed within a month. More recently, Nielsen and Petri (1963) have described the case of a woman of 77 with symmetrical gangrene of the fingers. At necropsy she was found to have a malignant neoplasm of the colon with cervical metastases infiltrating the stellate ganglion. The authors thought that the digital necrosis was the result of vasospasm due to sympathetic irritation.

Raynaud's Phenomenon

Impairment of the circulation in the fingers has been well recognized since Maurice Raynaud published his first thesis entitled "Local Asphyxia and Gangrene of the Extremities" in 1862. It is clear that the cases which he described represented a number of different disease processes. Nevertheless the term "Raynaud's disease" gained common usage, and it is hardly surprising that it cannot be defined. Lewis and Pickering (1933–4) suggested that the term "Raynaud's disease" should be abandoned and that "Raynaud's phenomenon" should be retained, defining it as "the active and intermittent closure of small arteries of the order of digital arteries supplying the extremities." They described the changes in colour, temperature, and sensation that characterize the phenomenon. Many people experience the phenomenon without ever showing any evidence of structural change in the vessels, but, in some, structural changes occur and lead to nutritional changes and tissue loss. In addition to those patients with Raynaud's phenomenon in whom no predisposing cause can be found, these changes may occur in association with systemic illness. Recognized as giving rise to secondary forms of Raynaud's phenomenon are obliterative arterial disease, thoracic outlet syndrome, occupational trauma, collagen diseases (especially scleroderma), ergot poisoning, and haematological diseases (particularly where cryoglobulins and cold agglutinins are found) (Gifford, 1963).

Previous to the work of Lewis and Pickering it was widely believed that digital ischaemia occurring in association with malignant disease was due to the involvement of the cervical sympathetic trunk by neoplasm, with resulting peripheral vasoconstriction. Lewis and Pickering showed that the ischaemic changes could not be due to sympathetic overactivity but were attributable to local spasm of the digital arteries, which were shown to be unduly sensitive to cold. The essential feature of the phenomenon is that it is intermittent and the term should not be applied to permanent changes in colour, temperature, and sensation. Lewis and Pickering also described cases of bilateral gangrene of digits, and of particular relevance to the present paper are their two examples of a "curious malady" which "customarily starts without warning, several fingers or toes becoming discoloured within a period of several days. The part attacked is not affected transiently or intermittently, but remains discoloured until, after weeks or months, it recovers colour, usually with loss of tissue at its end by a process of dry gangrene." In their examples there was no evidence of vascular disease proximal to the digital vessels, which they assumed on the basis of their tests to be thrombosed. It is our suggestion that an incident of this sort should alert the physician to the possibility of latent cancer. Lewis and Pickering and others have recognized digital ischaemia as a complication of advanced malignant disease but not as a feature of early or symptomless cancer.

Other Features

In the cases described above a number of features are worthy of mention. All of the patients were women and their digital symptoms were relatively late in onset, the youngest being 42 when first seen. None gave a previous history or family history of Raynaud's phenomenon. Symptoms were bilateral in five cases and affected two fingers on one side only in the other. In all cases the symptoms were sudden in onset and, with the exception of cases 3 and 5, rapidly progressed to gangrene. The site of origin of the primary tumour does not appear to be of significance: primaries were located in the maxillary antrum, kidney, and ovary respectively in three cases; one patient had carcinoma of both the colon and the corpus uteri; and in another case the organ of origin was not established but was probably the ovary or pancreas. In the remaining case the patient suffered from Hodgkin's disease. It is of interest that Case 3 had had a carcinoma of the rectum 10 years previously but at that time did not develop symptoms in her fingers. Three cases presented with digital symptoms; in the other three digital symptoms overshadowed earlier but milder symptoms which in retrospect were related to the underlying neoplasm. In Cases 3 and 5 the attacks of ischaemia were intermittent, but only in the former did the typical triphasic response to cold of Raynaud's phenomenon occur. In all others ischaemia was persistent though showing a tendency to improve.

There is no evidence that any of the predisposing conditions described by Lewis and Pickering were present in our series. Proximal arterial block could be excluded on clinical grounds in five cases, and in Case 1 an arteriogram showed the major vessels to be patent. In four cases reactive hyperaemia tests showed normal vasodilatation down to the proximal interphalangeal joints of the involved fingers. In those in which gangrene occurred, arterial occlusion is likely to have been caused by intense digital artery spasm, and this is supported by the fact that in some cases cold seems to have been a precipitating factor. Alternatively, ischaemia could have been the result of peripheral intravascular thrombosis. Venous thrombosis occurring in some forms of malignant disease is well recognized. Though the cause of this has not been established it seems at least possible that the same factors may operate to produce thrombosis in peripheral arteries in which the circulation has been rendered sluggish by cooling. Even so, it would be surprising if such a predisposition to thrombosis did not also show itself in episodes of phlebothrombosis. None of our patients developed symptoms or signs suggestive of venous thrombosis. It seems more likely that in those cases in which gangrene ensued vascular occlusion was the result of arterial thrombosis superimposed on spasm rather than the outcome of increased coagulability of the blood.

Vascular occlusion by emboli is unlikely in the absence of any discoverable predisposing lesion. In no case was there evidence of large-vessel or cardiac disease which might have given rise to emboli. It would also be difficult to explain the symmetrical and bilateral cases on the basis of embolism. There was no history of ergotism, and none of the patients had received drugs with vasoconstrictor effects such as methysergide.

Cryoglobulinaemia, a rare condition, may lead to intolerance of cold, peripheral gangrene, and allergic phenomena (Mackay *et al.*, 1956). These abnormal globulins can occur in multiple myeloma, lymphoma, and occasionally in other malignant disease. It is of interest that in the case of Domz and Chapman (1961) resection of the tumour led to a fall in the level of circulating cryoglobulins. The level, however, remained high and the cryoglobulinaemia could have been due to the coexisting myelofibrosis. Waldenström (1961) found that in 276 unselected cases of macroglobulinaemia 10 suffered from malignant disease. He concluded that the finding of macroglobulins in any patient should warrant further investigation to exclude neoplasm. Bohrod (1957) thought that cryoglobulinaemia, which can occur together with plasmacytosis and urticaria, represented an immunity reaction between tumour and host. In our cases cryoglobulins were looked for in all patients except Case 1, and in her case the electrophoretic strip was normal. They were found to be present only in Case 6, who suffered from Hodgkin's disease.

On the basis of the six cases described above it is suggested that malignant disease may give rise to digital ischaemia, and this may be the presenting or the only symptom. How this occurs is a matter for speculation. The incidence of "Raynaud's disease" in the older age groups of the general population is not known. It is possible that the occurrence of attacks of blue and numb fingers in association with malignant disease was coincidental in cases 3 and 5. The presentation in the remaining four cases, in which necrosis was an early feature and the onset more or less sudden, is unusual enough to suggest a more than fortuitous relationship. All of these patients with the exception of the case of Hodgkin's disease died within 18 months of the onset of the ischaemic changes. In some the malignancy remained undiagnosed until the patient's death and in others was advanced when eventually discovered. Patients who present with digital ischaemia, often loosely termed "Raynaud's disease," in whom the accepted causes have been excluded, deserve the fullest investigation in an attempt to discover an occult neoplasm.

The variety of neoplasms described in our series would suggest that the search must be wide and may even necessitate laparotomy in certain cases. If thorough investigation proves negative a careful follow-up should be undertaken. In two further cases not described in this series, the patients presented with digital ischaemia and remained undiagnosed despite the fullest investigation. They were well at nine months and three years respectively from the onset of their symptoms. In such cases a careful follow-up should always be undertaken. If the possibility of occult neoplasm as a cause of digital ischaemia is kept in mind diagnosis may be hastened and radical treatment made possible.

Summary

Six cases are described suggesting an association between digital ischaemia and malignant disease. They were a group of middle-aged women who either presented with atypical Raynaud's phenomenon or in whom this was a prominent feature. The symptoms were of sudden onset, bilateral in five cases, and in four rapidly progressed to gangrene. None of the commonly accepted causes of digital ischaemia was present. On investigation three patients were found to have a primary carcinoma of the maxillary antrum, kidney, and ovary, respectively; one patient had primary carcinomata of both the colon and corpus uteri, and in another the origin was not established but was probably the ovary or pancreas; the remaining patient was suffering from Hodgkin's disease. All of the patients with the exception of the last died within 18 months of the onset of the ischaemic changes. In some the malignancy remained undiagnosed until the patient's death and in others was advanced when eventually discovered. It is suggested that malignant disease may give rise to digital ischaemia and that it may be the presenting or only symptom. Patients who suddenly develop "Raynaud's disease" in whom the accepted causes have been excluded deserve the fullest investigation in an attempt to discover an occult neoplasm.

We wish to thank Professor R. S. Pilcher for his advice and encouragement in the preparation of this paper. We are also grateful to Professor Sir Max Rosenheim, Dr. E. E. Pochin, Dr. K. E. Harris, Dr. Matthew Steel, and Mr. D. R. Davies for permission to publish details of those cases which were under their care.

Solar Retinopathy

A. E. A. RIDGWAY, M.B., B.CHIR.

[WITH SPECIAL PLATE]

Brit. med. J., 1967, 3, 212–214

Five cases of solar retinopathy presenting in Oxford within three months of the partial eclipse of 20 May 1966 are described.

Pathogenesis

Of the sum of solar radiation reaching the surface of the earth, only the visible and short infrared wavelengths reach the retina, the ultraviolet and longer infrared rays being absorbed in the cornea and lens (Verhoeff *et al.*, 1916; Irvine, 1945). The 60 to 70% of solar energy reaching the retina is absorbed by its pigment epithelium with the liberation of heat. With a meiosis of 2 mm., a 30-second exposure leads to the production of heat at a rate of 70 calories/sq. cm./min., which is more than enough to produce a severe retinopathy experimentally (Verhoeff *et al.*, 1916; Ludvigh and McCarthy, 1938; Eccles and Flynn, 1944).

Exposure of pigmented rabbit retinae to xenon arc photocoagulator light has been shown to produce very similar lesions to human solar retinopathy, but similar exposures of albino rabbit retinae were tolerated without damage, and ten times the dose was needed to produce equivalent burns (Geeraets *et al.*, 1962; Geeraets and Ridgeway, 1963).

Further experimental work with xenon and carbon arc photocoagulators, the emissions of which are close to that of sunlight, has shown that the earliest damage is pyknosis of pigment epithelium cells with loss of fine structure in rods and cones, and local oedema, which may cause bulging of the retina into the vitreous cavity with resolution after a few days (Ham *et al.*, 1958).

The other factors influencing the severity of solar retinopathy are the intensity of the incident light—never less than 60% of full sunlight in the eclipse of 20 May 1966—and the duration of exposure.

Reflex meiosis of the order of 1.6 to 2 mm. (Verhoeff *et al.*, 1916) and refractive error tend to protect against damage. It has been shown that uncorrected myopes, who do not focus the sun's image on the retina, are relatively protected by reason of the lower density of illumination of the exposed areas (Das *et al.*, 1956). Physiological movements of fixation result in the exposure of a crescentic arc of retina on sun-gazing with a central zone always exposed and a peripheral zone intermittently exposed. Lastly, constancy of exposure is of importance in that repeated short exposures at short intervals do not summate in effect because of the good thermal conduction away from the macular area by its excellent blood supply.

Case 1

A 21-year-old labourer looked at the eclipse with both eyes without any protection for "about five minutes." He presented on 22 May 1966 complaining of dazzling when looking into the distance.

On examination the right visual acuity (R.V.A.) was 6/12 unaided, and the left visual acuity (L.V.A.) 6/9 unaided. On refraction both eyes were emmetropic, he had no strabismus, and no scotoma was demonstrable in either visual field. There was slight prominence of both maculae, and he was offered no treatment.

Progress.—His right macula became more prominent over the next three days and then subsided, and by 3 June was thought to be within normal limits. His symptoms improved and on 17 June his visual acuity was 6/4 unaided in both eyes, and his only complaint was that he had to alter fixation to read the middle two letters of the bottom row of the test chart with each eye. It was impossible to demonstrate a scotoma objectively in either eye, but ophthalmoscopically minute yellow spots were visible at both maculae.

Case 2

A 19-year-old male undergraduate reading physics presented on 24 May, having watched the eclipse through a plain glass window for a few seconds, and with sun-glasses for half a minute. He complained of a black spot in his right central field.

On examination the R.V.A. was 6/4 and the L.V.A. 6/9 (parts) uncorrected. On refraction the right eye was emmetropic and the left 0.25 dioptre sphere myopic, with which correction he achieved 6/4. He had no strabismus. Projection campimetry showed a small scotoma across and below fixation to a 3/2000 mm. red object, using a green fixation object and coloured goggles, green before the left and red before the right eye (Gambs *Perimeter Handbook*, p. 10, 1966). He had moderate macular oedema in the right fundus. He was treated with prednisolone 5 mg. three times a day.

Progress.—Over the next two weeks the macular oedema cleared and the prednisolone was tailed off and stopped. On 15 June his black spot was smaller and less dense, he had no visible macular abnormality, and on campimetry the scotoma was minute.

Case 3

A manual worker aged 36 presented on 22 May after watching the eclipse "for a few minutes" with his right eye through the gaps between his fingers. He complained of blurring of central vision.

On examination the R.V.A. was 6/6 (parts) and the L.V.A. 6/4. On refraction the left eye was emmetropic and the right eye had one dioptre sphere of hypermetropia. With this correction his R.V.A. was 6/5. He had no strabismus.

Projection campimetry showed a circular blurred area to 10 degrees from fixation and he had gross perimacular oedema. He was started on prednisolone 10 mg. three times a day by mouth.

Progress.—On 24 May the perimacular oedema was less but there was a swelling at the macula (Special Plate, Fig. 1). On 27 May the oedema had receded further and there was a definite macular cyst. The prednisolone was reduced to 10 mg. twice daily. On 1 June his blurred patch was much smaller but considerably denser and a scotoma of 1 degree diameter was demonstrated at fixation to a 3/2000 mm. red object. The R.V.A. had dropped to 6/9 corrected. The prednisolone was tailed off and stopped over the next seven days. During the next two weeks the macular cyst became smaller, as did his scotoma, and on 17 June he managed R.V.A. 6/5 corrected, scanning the smaller letters.

Case 4

A schoolboy aged 13 presented on 11 August complaining of blurring of vision in the right eye after viewing the eclipse. He had gazed at the sun through two sun-glasses for two to three minutes between classes. Three hours later he noticed green flashes in the right eye and that evening his vision in this eye became very blurred. It had now recovered somewhat.

On examination the R.V.A. was 6/6 (parts) and the L.V.A. 6/4. Both eyes were emmetropic and there was no strabismus. Campimetry showed a small scotoma between one and two degrees, nasal to (binocular) fixation and extending five degrees up from the horizontal meridian. He had a flat lesion below a moderate-sized paramacular hole in the right fundus.

Progress.—In view of the lateness of presentation no treatment was offered, and to allay parental anxiety follow-up has been deferred for six months.

Case 5

An accounting-machine operator aged 25 presented on 3 June. She had been sunbathing without sun-glasses five days previously, and had been "squinting at passers-by against the sun" through her left eye. On awaking the next morning she had noticed a shimmering patch in her left central field, which had become smaller and was now opaque.

For 10 years she had had migraine two to four times a year. This consisted of flashing lights in the right eye spreading to the left, followed by a generalized headache not relieved by aspirin.

On examination the R.V.A. was 6/5 and the L.V.A. 6/36+2. On refraction both eyes were emmetropic and she had no strabismus. Campimetry showed a crescentic scotoma in the upper and lateral macular region and she had much macular and perimacular oedema maximal below a small macular hole (Special Plate, Fig. 2). She was treated with prednisolone 5 mg. four times a day by mouth.

Progress.—On 11 June her field defect had contracted to a 2 by 1 degree scotoma across and above fixation on projection campimetry to a 3/2000 mm. red object, and her L.V.A. had improved to 6/18 unaided. The macular oedema had disappeared and the macular hole was less prominent. Her corticosteroids were tailed off over the next week. On 17 June her L.V.A. had improved to 6/9 part unaided and she was no longer conscious of the field defect, which was unchanged. There was some fine pigmentation around the macular hole.

Discussion

The first four cases demonstrate the damage which may be caused by short exposure of the retina to the sun. In the past, damage caused by watching eclipses has been related to similar changes seen in people who have looked at the sun for other reasons.

Das *et al.* (1956) reported cases among Punjabis who look at the sun for religious reasons. Pittar (1943) reported one case in an anti-aircraft gunner firing at an enemy plane flying out of the sun, and fighter pilots performing the same manœuvre have suffered similar consequences. Irvine (1945) has recalled the case of a seaman "steering into the sun's eye." Bates (1920) advocated prolonged sun-gazing as the treatment of myopia, with disastrous results.

However, solar retinopathy takes on a much more sinister aspect with the presentation of the fifth case. Here a healthy young woman was sunbathing, and it seems probable that as a consequence of this innocent act she sustained a severe macular burn, leaving her with a permanent central field defect in one eye, an anatomical lesion, and possibly the predisposition to macular degeneration in this eye in later life (Corcelle, 1958).

The warnings made by Knudtzon (1948) need repeating, especially as they bear on the false sense of protection afforded by dark glasses, red glass filters, smoked glass, and overexposed negative films. The only safe way of observing the sun, the method used by astronomers, is to project the sun's image on to a screen. For the amateur a pin-hole and sheet of matt paper held in the shade behind it will suffice (Gilkes *et al.*, 1961).

In the case of accidental solar retinopathy it is difficult to suggest any protective measure other than greater public awareness of the dangers involved. Publicity before the eclipse of 20 May 1966 was responsible for much sun-gazing, and no safe protective methods were advocated. In effect, interest was aroused and the dangers were minimized.

Summary

Four cases of eclipse burn and one of solar retinopathy due to sunbathing are presented. The seriousness of an apparently trivial action in terms of visual function is demonstrated and attention is drawn to the possibility of accidental macular burns.

More effective methods of prevention are advocated and it is urged that public awareness of the dangers be aroused.

I wish to record my thanks to Messrs. J. P. F. Lloyd, V. Purvis, and A. C. L. Houlton for permission to report cases under their care, to Mr. T. Ramsell for much critical assistance, and to Mr. E. W. Allen and his staff for the photography.

Effect of Oral Contraceptives on Erythrocyte Sedimentation Rate in Healthy Young Women

J. Ll. BURTON,* M.B., CH.B., B.SC., M.R.C.P.

Brit. med. J., 1967, **3**, 214–215

The erythrocyte sedimentation rate (E.S.R.) is a useful non-specific test for a variety of diseases accompanied by inflammation or breakdown of tissue. It is often used as a screening test for occult disease in the absence of physical signs, and it is also useful for assessing progress in chronic or relapsing disease.

A recent reply in the "Any Questions?" column of the *British Medical Journal* (25 March 1967) has implied that the E.S.R. in women taking oral contraceptives is normal. It has long been known that the E.S.R. is raised above the usually accepted limits of normal in pregnancy (Fåhraeus, 1918; Bochner and Wassing, 1925; Dawson, 1960), and since the physiological effects of oral contraceptives are in many ways similar to those of pregnancy it was decided to investigate their effect on the E.S.R. in normal young women.

Methods

Women attending a routine family planning clinic were divided into two groups according to whether they used oral contraceptives[1] or an occlusive pessary. After a medical interview a 2.5-ml. sample of venous blood was obtained for the estimation of haemoglobin, packed cell volume, and E.S.R.

All women included in the final study conformed to the following criteria: (1) they were below 40 years of age; (2) they had been using the same contraceptive method for at least six months previously; (3) they gave no history of previous serious or chronic illness, and had not suffered from overt infection during the previous four weeks; (4) they felt perfectly well on the day of attendance at the clinic; and (5) they had haemoglobin levels and packed cell volumes within normal limits (Hb 11.5–16.4 g./100 ml.; P.C.V. 36–47%).

The relation of the timing of the blood sample to the menstrual period was not determined, since this was a random variant in both groups, and in any case the fluctuation of E.S.R. with menstruation is insignificant (Greisheimer, 1927; Wintrobe, 1961).

Seventy-eight women were included in the study, of whom 42 had been taking oral contraceptives and 36 had been using an occlusive pessary.

The blood samples were transported in polystyrene bottles containing Sequestrene anticoagulant, and the E.S.R. was determined within six hours by the Westergren method, a one-fourth part of 3.8% sodium citrate solution (Dacie and Lewis, 1963) being used. Various authors have given results varying from 7 to 25 mm. in the first hour for the upper limit of the normal E.S.R. in women (Westergren, 1926; Dawson, 1960; Dacie and Lewis, 1963; Hilder and Gunz, 1964; Böttiger and Svedberg, 1967). The normal value used in this laboratory for young women is up to 7 mm. in the first hour (Dacie and Lewis, 1963), and this is also the value proposed by the British Standards Institution Technical Committee on Haematological Equipment and Methods (Lewis, 1965).

---

* Assistant Lecturer, Department of Medicine, the Royal Infirmary, Edinburgh 3.

[1] The oral contraceptives used in this study were: Ovulen (mestranol 0.1 mg. and ethynodiol diacetate 1 mg.), Lyndiol (mestranol 0.15 mg. and lynoestrenol 5 mg.), Lyndiol 2.5 (mestranol 0.075 mg. and lynoestrenol 2.5 mg.), and Gynovlar (ethinyloestradiol 0.05 mg. and norethisterone acetate 3 mg.).

Results

The results are presented in the Table. Of the 42 women taking oral contraceptives 19 (45%) had an E.S.R. above our upper limit of normal, the highest value recorded being 17 mm. in the first hour. None of the patients in the control group had an E.S.R. exceeding 7 mm. The mean value for the E.S.R. in the group taking oral contraceptives was 7.2 mm. in the first hour, compared with 4.0 in the control group, and this difference was statistically significant ($P<0.02$).

Westergren E.S.R. (mm. in First Hour)

Women in Control Group			Women Taking Oral Contraceptives			Student's *t* Test
Mean	Range	S.D.	Mean	Range	S.D.	
4·0	1–7	1·9	7·2	2–17	4·4	$0{\cdot}02>P>0{\cdot}01$

Discussion

The E.S.R. depends on the rate of erythrocyte rouleaux formation, which in turn depends on the plasma concentration of asymmetric macromolecules such as fibrinogen, and to a less extent on α_2- and γ-globulins (Hardwicke and Squire, 1952). Rouleaux formation is probably mediated by a specific plasma protein called "agglomerin," which requires the presence of a supplement of high molecular weight such as fibrinogen for its action (Ruhenstroth-Bauer, 1961). The E.S.R. thus supplies a simple screening test for the presence of raised concentrations of large molecules such as fibrinogen and the larger globulins.

The rise in E.S.R. which accompanies normal pregnancy is attributable to the increased concentration of fibrinogen, which is well documented (Gillman *et al.*, 1959 ; Ratnoff and Holland, 1959 ; Pechet and Alexander, 1961). Similar increases in fibrinogen concentration have been reported in women taking oral contraceptives (Rapaport, 1962 ; Donayre and Pincus, 1965 ; Miller *et al.*, 1965), and this probably accounts for the increased E.S.R. demonstrated in the present study. The effect of hormonal influences on the E.S.R. merits further investigation, however, since Böttiger and Svedberg (1967) have shown that the normal increase in E.S.R. with advancing age is accelerated after the menopause.

These results are reported in order to draw attention to the fact that the E.S.R. may be raised above normal in women taking oral contraceptives and that the isolated finding of a moderately raised E.S.R. is not necessarily an indication for further investigation. Similarly, the assessment of chronic disease by changes in E.S.R. may need to be modified if it is known that the patient is taking oral contraceptives.

Summary

The Westergren erythrocyte sedimentation rate (E.S.R.) was determined in 42 healthy young women taking oral contraceptives. The mean E.S.R. was significantly higher than in a control group of the same age, and 45% of the women taking oral contraceptives had an E.S.R. above the upper normal limit for their age.

The finding of a slightly raised E.S.R. in an otherwise healthy young woman taking oral contraceptives is not an indication for further investigation.

ADDENDUM.—Since the above report was submitted for publication E.S.R.s in the range 17–36 mm./hr. have been discovered in a further five women taking oral contraceptives who conformed to the above criteria.

Thanks are due to Dr. Nancy Loudon and the staff of the Edinburgh Family Planning Centre, and to Dr. S. H. Davies and the Department of Haematology, Royal Infirmary, Edinburgh.

Treatment of Radiation Sickness with Pyridoxine Hydrochloride in Outpatients of a Radiotherapy Unit

H. MATTIE,* M.B. ; E. W. EMERY,† F.F.R. ; I. D. HILL,‡ B.SC. ; D. R. LAURENCE,§ M.D., F.R.C.P.

Brit. med. J., 1967, **3**, 215–216

Since Maxfield *et al.* (1943) reported "most satisfying" results with intravenous pyridoxine hydrochloride in patients with radiation sickness the vitamin has become widely used in this condition, more often administered orally than parenterally (Reeves, 1946 ; Oppenheim and Lih, 1946 ; Wells and Popp, 1947 ; Shorvon, 1949 ; Strahm, 1955 ; Silverman *et al.*, 1956 ; Stoll, 1957 ; Finney, 1961).

However, so far as we know, of the many reports on this treatment only a few are based on properly controlled studies: one study with rather low dosages (Silverman *et al.*, 1956), and another with breast cancer patients only (Finney, 1961). These authors found no difference between pyridoxine and a placebo.

The study reported here was devised in an attempt to reassess the value of pyridoxine.

Design of the Trial

Since radiation sickness manifests itself as a complex of subjective, often vague, complaints, mixed with symptoms due to the original disease or to anxiety, it is obvious that a study of the effect of treatment should be conducted double-blind, and this was done.

† Department of Radiotherapy, University College Hospital, London W.C.1.
‡ Medical Research Council, Statistical Research Unit, London W.C.1.
§ Medical Unit, University College Hospital Medical School, London W.C.1.

Hitherto in the radiotherapy department of University College Hospital patients who complained of anorexia, nausea, and malaise received pyridoxine treatment routinely, 25 mg. t.d.s., direct from the radiotherapist, who distributed it from a central source of supply. If this was insufficient the patients were referred to a physician for further treatment, generally by recognized antiemetics—for example, meclozine, promazine, etc. Our aim was to keep this simple routine intact, and to ask nothing more of the radiotherapist than to keep a record of the patients' complaints and of their drug treatment, for the department is busy and a design interfering with the routine would have been unacceptable. We did not think it proper to use a dummy tablet, as the radiotherapists' general conviction was that pyridoxine was an effective drug. Therefore we used two different dosage levels: 1-mg. and 50-mg. tablets,[1] at first 1 tablet t.d.s., but the radiotherapist could double the dose on her own initiative if the patient did not respond. Thus the maximum daily dose with the low-dosage tablets—that is, 6 mg.—was somewhat more than the biological need, while with the high-dosage tablets it was 300 mg., which is more than had been ordinarily given in the department.

To minimize interference by other drug therapy we included only outpatients in this trial; inpatients tend to be on a larger number of drugs, and patients were excluded afterwards if they did take other drugs or if they did not take pyridoxine regularly. Moreover, patients who were treated for diseases of skin or joints were not included, as they are rarely troubled by radiation sickness, so that nearly all patients were being treated for malignant diseases—for example, cancer of the lung or the breast, Hodgkin's disease, etc.

The duration of the whole trial was 24 weeks, divided into eight three-week periods. During each period the central source of tablets contained either all high-dose tablets or all low-dose. There were four periods of high and four of low in the total of eight periods in the order HLLHLHHL. Patients were supplied with bottles containing 15 tablets at a time. Patients ordinarily attended for radiotherapy five days a week.

Results

Of the 202 patients initially included 19 were excluded, for reasons given above, after radiotherapy was started. Of the remaining patients 94 had symptoms which justified treatment with pyridoxine; 89 patients never needed pyridoxine.

First the effects of high- and low-dose tablets in the dosage of 1 tablet t.d.s. were compared. If the complaints were controlled—that is, it was not thought necessary to give 2 tablets t.d.s.—or remitted on this dosage a "success" was recorded, otherwise a "failure." Twelve patients could not be used in this scheme, as they changed from the high- to the low-dose tablets, or vice versa, between starting and the occurrence of a success or a failure. This was an inevitable consequence of the use of a single central supply source.

The remaining 82 patients are included in the following Table:

	Success	Failure	Total
High dose	36	10	46
Low dose	22	14	36
	58	24	82

The higher success rate with the high dose (78%, against 61% for the low dose) is not statistically significant (P=0.14) at the generally accepted level. If there was no real difference between high and low doses such a result would occur by chance once in seven times.

As the periods in which two tablets were used are inevitably correlated with the preceding periods on 1 tablet t.d.s., we did not think it proper to make any analysis of this dosage. Moreover, the number of failures—that is, when the patient did not improve while taking pyridoxine—was so low that this test would be unlikely to uncover a difference between the two dosages; 31 patients were treated with the double dose and only 7 of these reported failure (3 out of 13 for the high dose and 4 out of 18 for the low dose). This failure rate was much lower than was anticipated from our previous experience (we roughly estimated that half of all patients should need more potent drugs), and we attribute this to the therapeutic enthusiasm of the radiotherapists participating in the trial. As a matter of fact the failure rate was about the same as that in several of the above-mentioned uncontrolled studies (8–12%).

Conclusion and Summary

We think that the practical conclusion should be that treatment of radiation sickness with 1 or 2 mg. of pyridoxine hydrochloride orally t.d.s. by radiotherapists who are convinced of its efficacy gives very good results. Whether the effect of this low dose would differ from a placebo remains to be seen.

The effect of the treatment of radiation sickness with pyridoxine hydrochloride was studied in outpatients of a radiotherapy unit. No significant difference between a very low (1 mg. t.d.s.) and a high dose (50 mg. t.d.s.) was detected. When, in case of failure of these doses, the daily dose was raised to 2 mg. t.d.s. and 100 mg. t.d.s., only a few patients in either group had to be treated with more potent drugs.

We are grateful to Sister Plowman and her staff for their enthusiastic participation; to Miss Kingsbury and her staff; and to Mr. A. R. Williams, pharmacist to the hospital, who provided the tablets.

[1] 10 mg. of ascorbic acid and 0.5 mg. of quinine sulphate were added to all tablets to mask the taste of the higher dosage of pyridoxine hydrochloride.

Medical Memoranda

Case of Englemann's Disease

[WITH SPECIAL PLATE]

Brit. med. J., 1967, 3, 217

Englemann's disease is one of the rarest bone dystrophies causing osteosclerosis. The first case was published by Englemann in 1929. A search of the literature has revealed 53 cases reported up to 1964. However, there has hardly been any record of a similar case in the Indian literature. The purpose of this paper is to report a case of Englemann's disease and to review the literature on the subject.

CASE REPORT

A girl aged 14 was admitted to our medical unit of Irwin Hospital, New Delhi, with the object of investigating the cause of her stunted growth. Her father had noticed that her growth had not been up to the mark since the age of 4 years. She had had slight pain in the legs for one year. Her developmental milestones were normal except that she started walking at the age of 2 years. Past and family history were non-contributory. The outstanding features on general examination were a short stature, a waddling gait, and the absence of secondary sex characters. She had not started menstruation and her genitalia appeared infantile. Her height and span were below average for her age and her crown-to-rump and rump-to-heel ratio was 1.2:1. Local examination revealed thickening, tenderness, and venous prominence over both tibial bones. The ulna was irregularly palpable on both sides. Examination of nervous, cardiovascular, respiratory, and gastrointestinal systems showed nothing abnormal.

Investigations.—Haemoglobin was 12.0 g./100 ml., total leucocyte count 7,700/cu. mm. (polymorphs 50%, lymphocytes 49%, eosinophils 1%), erythrocyte sedimentation rate 9 mm. in first hour (Westergren). Urine and stool examinations showed nothing abnormal. Serum alkaline phosphatase was 4.1 K.A. units, serum calcium 11.2 mg., serum phosphorus 3.7 mg., blood urea 23 mg., and serum cholesterol 150 mg./100 ml., glucose-tolerance curve normal. Twenty-four-hour excretion of fat in stool was 3.5 g., and 24-hour excretion of 17-ketosteroids in urine was 5.9 and 3.2 mg./100 ml. Basal metabolic rate was +8. Mantoux test was positive. Buccal smears for sex chromosomes was positive (female type). Radiological changes were seen in the diaphysis of all the long bones as well as in the skull bones. Bones of hands, feet, clavicle, ribs, spine, scapulae, and pelvis did not show any changes. The typical findings were in the form of cylindrical expansion of the whole of the diaphysis due to cortical thickening which reduced the width of the medullary canal (Special Plate, Figs. 1 and 2). The metaphysis and epiphysis were left unaffected. The skull showed gross thickening and sclerosis of the frontal bones, particularly the supraorbital margins, extending towards the forehead as well as to the floor of anterior and middle cranial fossae and backwards to the petrosal ridge. The parietal and frontal bones showed patchy areas of sclerosis (Special Plate, Fig. 3). Biopsy from the affected bone showed moderate thickening of the bony trabeculae with normal laying down of osteoblasts.

COMMENTS

Englemann's disease is characterized by underdevelopment due to fusiform expansion and sclerosis of the diaphysis of long bones. The disease is diagnosable in infancy and may be suspected in any child with feeding problems and delayed walking. The youngest patient reported by Gvozdanovic (1950) was a 3-months-old girl. During childhood aching limbs and a wide-based waddling gait are characteristic features. Delayed puberty associated with or without skeletal deformities and a variable degree of neurological deficit are common in later life (Riley and Shwachman, 1943). The disease, as in the present case, is often discovered accidentally.

A multitude of laboratory tests revealed no abnormality. However, radiological changes are diagnostic. Classical changes start in the diaphysis of long tubular bones with spindle-shaped sclerotic thickening, and as the age advances osteosclerosis extends lengthwise but the metaphysial and epiphysial zones are usually not affected, though Clawson and Loop (1964) described an unusual case showing widening and osteoporosis of these areas as well. The characteristic changes have been seen mostly in the long bones of extremities, but others are also involved. However, Lennon *et al.* (1961) in a review of 52 cases described the involvement of the base of the skull in 53%, cervical vertebrae in 9.6%, and metatarsals and metacarpals in 9.6%. Long bones as well as skull bones are involved in our case.

The histological picture is very variable (Neuhauser *et al.*, 1948 ; Bingold, 1950). The changes, whenever present, are confined to the radiologically altered areas of bone and consist mainly of cortical hyperostosis. Histologically, the disease has to be differentiated from infantile cortical hyperostosis, which occurs in infants and where the involvement of bone is asymmetrical and ribs and mandible are invariably involved (Caffey, 1956 ; Stewart and Cole, 1956).

The exact pathogenesis of the condition is not known. Englemann (1929) believed that it was caused by a disturbance of the haemopoietic system, but this belief has not been upheld by subsequent workers (Neuhauser *et al.*, 1948 ; Sear, 1948 ; Bingold, 1950 ; Griffiths, 1956). Some suggestion of pituitary deficiency mainly based on the occurrence of infantilism associated with diminished excretion of 17-ketosteroids in urine has been made by Jammes *et al.* (1953) and Buchem *et al.* (1955). However, in our case urinary 17-ketosteroid excretion was within normal limits. The disease is often reported to be familial, though the genetic basis has not been fully worked out.

Phenindione-induced Neuropathy

Brit. med. J., 1967, 3, 218

Mononeuritis has been well recognized in diabetes, alcoholism, polyarteritis nodosa, carcinomatosis, and leprosy. Traumatic mononeuritis was not uncommon during wars. Of the blood disorders haemophilia, thrombotic thrombocytopenic purpura, porphyria, macroglobulinaemia, and myelomatosis are too well known. Two cases of neuropathy due to anticoagulant therapy are reported.

CASE 1

The patient, an old case of malignant hypertension (for which he had had a sympathectomy 13 years previously, followed by control of blood pressure on hexamethonium), was admitted to hospital on 22 May 1963 with a history of sudden onset of retrosternal pain lasting for 45 minutes. Diagnosis of myocardial infarct was confirmed by E.C.G. He was given analgesics, sedatives, and anticoagulants—heparin 10,000 i.u. stat. and 5,000 i.u. six-hourly for five doses intravenously, along with phenindione 200 mg. stat. and 150 mg. next day. The prothrombin time was 17 seconds with a control of 13 seconds on 23 May ; subsequently it was controlled two to two and a half times the control (prothrombin time ranging from 24 to 32 seconds against a control of 12 to 16 seconds), with varying doses of phenindione ranging from 25 to 50 mg. twice a day. On 8 June he complained of severe pain in his right buttock and thigh. On examination there was evidence of right sciatic nerve palsy with motor and sensory changes. Later strength curves showed denervation. Haemoglobin was 14.4 g./100 ml. ; it dropped to 9 g., but returned gradually to normal. Prothrombin time was 24 seconds, with a control of 16 seconds. Prothrombin activity was raised by vitamin-K injections. Total W.B.C., blood urea, E.S.R., electrolytes, liver-function tests, serum proteins, and cerebrospinal fluid were normal.

He was treated with intensive physiotherapy and electrical stimulation of paralysed muscles. Severe pain continued, though after three months there was a good recovery of his hamstring muscles but little improvement in his leg muscles, and the right-foot drop was well marked. Sensations were impaired on the lateral aspects of the right leg and foot. Physiotherapy was continued along with analgesics and tranquillizers.

He was followed up for a year. He continued having pain similar to that encountered in some cases of brachial plexus palsy, with little recovery of muscles below the knee.

CASE 2

This patient, an old case of recurrent myocardial infarction, had been on long-term anticoagulants (phenindione) since his discharge from hospital on 5 June 1965. He was having 50 mg. of phenindione twice a day. His prothrombin time on 8 August was 32 seconds against the control of 14 seconds. While on holiday on 20 August he started having bruising and pain in his left arm, with tingling and numbness in his fingers. Examination showed the clinical picture of a complete median nerve lesion on the left side with motor and sensory features, though no bruising was seen at the time of examination. The lesion was thought to be in the arm between the origin of the nerve and the site of the first muscular branch in the antecubital fossa. Strength-duration curves showed denervation. Investigations included prothrombin time of 83 seconds against a control of 12, which fell to 17 after phenindione was stopped. Haemoglobin was 15 g./100 ml., total W.B.C. 11,000/cu. mm. Platelet count, bleeding-time, and coagulation-time were normal. Blood urea, electrolytes, liver-function tests, pyruvate metabolism test, serum proteins, electrophoresis, chest *x*-ray picture, and cerebrospinal fluid were within normal limits.

He was put on analgesics, after which he was admitted to hospital for a course of corticosteroid therapy to reduce fibrosis around and within the nerve, and electrical treatment. After six weeks' treatment the power in his left hand had improved, and sensations were impaired over the distal interphalangeal joints of thumb, index, middle, and medial half of the ring finger only. He continued to improve with physiotherapy and electrical treatment. Initially he also had a severe causalgic type of pain in the hand and forearm, but this improved with corticosteroid treatment.

COMMENT

Adverse reactions to phenindione are well known. Perkins (1962) reviewed 133 reported cases and three of his own. The most common complication was a rash (100 cases), fever (34 cases), diarrhoea (20 cases), granulocytopenia (18 cases), stomatitis (14 cases), jaundice (10 cases), and nephropathy (5 cases). Occasional cases had vomiting, misty vision, thrombocytopenia, lymphadenopathy, conjunctivitis, loss of hair, and gangrene of the breast. Devanney and Osher (1952) described a case of spontaneous spinal epidural haemorrhage. Further cases were mentioned by Jacobson *et al.* (1966), who added three of their own.

Haematuria and bruising are the presenting features of phenindione overdose in most of the patients. The above cases are of interest, because there was no history of trauma or subcutaneous haemorrhage formation, and I believe the spontaneous haemorrhage into the nerve sheaths due to an unknown local factor, resulting in ischaemic neuritis of the nerve, caused the palsy in both cases. Persistent pain in Case 1 was presumably due to fibrosis in and around the sciatic nerve. The cases differ in the fact that in Case 1 the anticoagulant control was reasonable, though in Case 2 the prothrombin time was prolonged. There was no history of trauma in either case. It is therefore unlikely that either trauma sensitivity to phenindione or prolonged prothrombin time was the sole factor, and the combination of both factors seems to have been more than likely.

I should like to thank Dr. W. A. Elliott, consultant physician, and Mr. R. H. Sewell, consultant orthopaedic surgeon, for allowing me to publish these cases, and for their necessary advice and guidance.

Current Practice

MEDICINE TODAY

Recognition of Heart Failure

"Medicine Today" is the television series for doctors produced by the B.B.C. Advice in the preparation of the programme is given by the Association for the Study of Medical Education.

The programme on B.B.C. 2 on 18 July was on the subject of heart failure and portable oxygen equipment for use in the home. Printed below is an article prepared with the help of expert contributors to complement the television programme, which will be repeated on B.B.C. 1 on 26 July at about 11.20 p.m.

In "Medicine Today" Dr. C. S. McKendrick discussed the recognition of heart failure and its long-term management. He pointed out that, though failure of both ventricles may occur simultaneously, the individual clinical presentations of right-sided and left-sided failure had their own specific characteristics and that the aetiological factors differed. Failure of the left ventricle tended to be acute and characterized by paroxysmal nocturnal dyspnoea or acute pulmonary oedema. It was commonly the result of ischaemic heart disease, hypertension, or aortic-valve disease. Failure of the right ventricle was associated with an insidious onset and characterized by a raised central venous pressure and later associated with oedema. It was usually due to pulmonary hypertension secondary to chronic respiratory disease or mitral-valve disease. The more insidious onset of right-sided failure was related to the enormous capacity of the systemic vascular bed as compared with that of the pulmonary vascular bed.

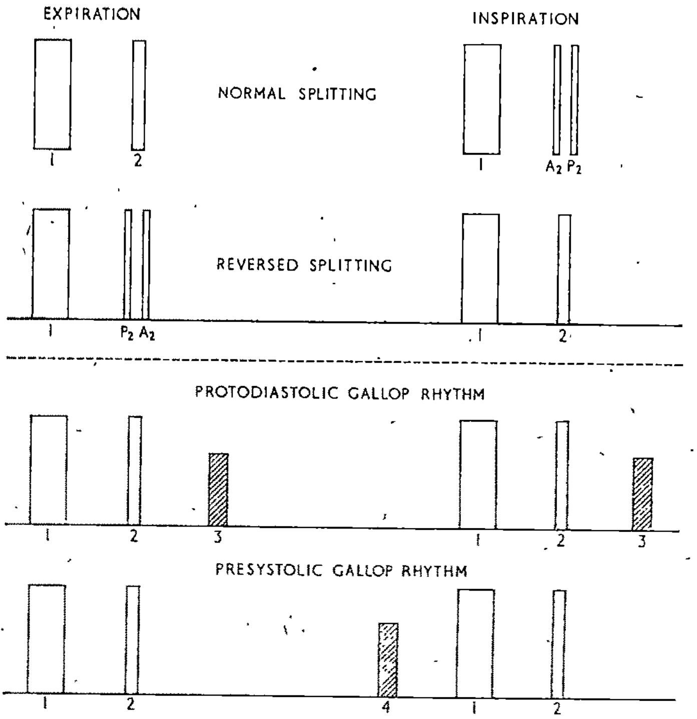
The more dramatic manifestations of heart failure, such as the crepitations of pulmonary oedema and the oedema of congestive cardiac failure, are well known and require no further comment. Moreover, the management of heart failure has frequently been discussed in these columns and will not be considered in this article. Certain points in the diagnosis of heart failure are, however, worthy of further consideration—in particular, gallop cardiac rhythm and the pattern of the jugular venous pulse.

Heart Sounds

The first heart sound is due to the closure of the mitral and tricuspid valves and is loudest at the apex. The second heart sound is due to the closure of the aortic and pulmonary valves and is loudest at the level of the second intercostal space. Splitting of the second heart sound (see Figure) during inspiration into an earlier aortic and a later pulmonary component is normally audible. The delayed closure of the pulmonary valve is due to the intrathoracic pressure falling during inspiration, which causes an increase in the venous return to the right ventricle. As a result of the increased stroke volume the right ventricle takes longer to contract and the pulmonary heart sound is heard after the aortic. Abnormally wide splitting will be heard if there is delay of pulmonary valve closure owing to right bundle-branch block or when the right ventricle ejects more blood than the left, as may occur with atrial septal defects. Sometimes left ventricular contraction is delayed because of left bundle-branch block. The closure of the aortic valve is then delayed and this also results in asynchronous closure of the aortic and pulmonary valves. Here the splitting is reversed and is heard during expiration instead of inspiration. Though split, these two sounds occur very closely together and should not be confused with a third sound, which occurs in mid-diastole.

The sounds of ventricular filling, sometimes called *triple or gallop rhythm,* comprise the atrial sound, the third heart sound, and a summation of the two. These sounds have a peculiarly low pitch, which distinguishes them from other heart sounds. The third heart sound, or *diastolic filling sound,* is due to the sudden stretching of the ventricular walls as the ventricle fills with blood—in much the same way as a noise is produced when the wind fills an empty sail. This sound is commonly heard in normal children and young adults but never in healthy subjects over the age of 40. Though this sound cannot be detected by auscultation in healthy persons of middle age, phonocardiograms demonstrate its presence. When ventricular filling is increased, as in mitral incompetence or in ventricular septal defects, and when constrictive pericarditis limits ventricular filling, the third heart sound becomes audible. More importantly it also becomes audible in ventricular failure when the atrial pressure is increased. In right ventricular failure the third sound is heard best in the tricuspid area over the right ventricle, while in left ventricular failure it is heard at the apex.

The fourth heart sound is caused by atrial contraction and indicates either atrial hypertrophy or enhanced atrial contraction owing to the increased resistance of the failing ventricle. This sound is often easier to feel than to hear.



Upper figure shows splitting of the heart sound. Lower figure shows third and fourth heart sounds.

When the heart rate is rapid the triple rhythm caused by the extra heart sound is called gallop rhythm (see Figure), because of its resemblance to the sound of a horse in canter. If it is due to a third heart sound the gallop rhythm is called *protodiastolic* and if it is due to a fourth heart sound it is called *presystolic*. Nevertheless, when the ventricular rate is very fast the third and fourth heart sounds become superimposed and their differentiation is not possible. The rhythm is then called a *summation gallop*. The real importance of these triple rhythms is that they are evidence of ventricular stress and incipient failure. But, as Dr. McKendrick pointed out, it is rarely necessary to differentiate which sort of triple rhythm is present. The important thing is to look for triple rhythm in anybody who is middle-aged and breathless and recognize it as evidence of ventricular failure. When the triple rhythm disappears it shows that the patient is improving, and if it persists in spite of treatment it is a bad prognostic sign.

The third and fourth heart sounds must be differentiated from another sound called the *opening snap*, which is pathognomonic of mitral stenosis. The snap is clicking in quality and precedes the mitral diastolic murmur characteristic of the valve disorder. It is due to the sudden opening of the anteromedial cusp of the mitral valve.

Raised Venous Pressure

Without depreciating the importance of gallop cardiac rhythm the first recognizable evidence of right ventricular failure is often a raised central venous pressure, and this can be detected long before oedema develops. It is best observed in the internal jugular vein. Because there is no valve between the internal jugular vein and the right atrium this vein accurately reflects pressure in the right atrium. In normal subjects lying down at an angle of 45 degrees the jugular veins are distended to a height of two or three centimetres above the sternal angle. To examine the venous pulse it is essential that the patient is relaxed, as the internal jugular veins lie deep to the sternomastoid muscles. The internal jugular is a better guide to centre venous pressure than the external jugular vein because kinking in the latter may mask the impulse.

A visible pulse in the neck may be arterial or venous, and it is of obvious importance to differentiate them. The carotid pulse is palpable, whereas a venous pulse is not. Furthermore, the carotid pulse has an abrupt onset and is more localized. A venous pulse rises during inspiration and normally has more than one peak. If in doubt pressure on the abdomen will raise a venous pulse but not affect the arterial pulse. Though this hepatojugular reflux has been described as a sign of cardiac failure, it is not reliable as such, for the difference in the normal subject and the patient in heart failure is quantitative and not qualitative.

Two waves may easily be detected in the normal venous pulse. The first is the "a" wave—which is due to atrial systole and occurs immediately before the carotid pulse. The second is the "v" wave of ventricular systole caused by the filling of the right atrium when the tricuspid valve is closed. The "a" wave will be increased when there is atrial hypertrophy, as in tricuspid stenosis, and it will be absent when there is atrial fibrillation. The "v" wave will be increased when there is tricuspid incompetence, whether this is organic from rheumatic heart disease or functional from dilatation of the right ventricle in heart failure.

Inspection of the jugular venous pulse thus not only indicates a raised central venous pressure, which is evidence of right heart failure, but also determines the presence of atrial fibrillation and tricuspid incompetence. It is an important physical sign to seek in patients with acute chest pain. Myocardial infarcts do not occur in the right ventricle, so that if acute chest pain is associated with a raised central venous pressure it is likely to signify pulmonary infarction and not coronary-artery disease.

TODAY'S DRUGS

Hazards of Drug Prescribing in Pregnancy

The common hazards of prescribing any drugs are further complicated in the pregnant woman. Both the embryo or foetus and the parent are susceptible to effects of therapeutic substances which under other circumstances might be expected to be without serious risk. One immediate response to the tragic experience with thalidomide was a reaction towards an attitude of relative therapeutic nihilism during pregnancy. While this, as will be seen, is probably an understandable and proper attitude to adopt towards newly introduced drugs, if followed too blindly it can lead only to discomfort for, or may even be detrimental to, the pregnant woman.

Teratogenic Drugs

The teratogenic capacity of a drug is one—fortunately limited—aspect of the problem. Such effects result from interference with the development of the embryo in early pregnancy. Nevertheless, the drugs *known* to be teratogenic in man are very few. Clearly the prescriber has a responsibility to avoid the use of such drugs in the first twelve weeks of pregnancy, and especially in the period of differentiation from the third to eighth week. Apart from thalidomide, these are drugs mainly used in the treatment of cancer—antimetabolites (such as methotrexate, 6-mercaptopurine, and allopurinol), alkylating agents (such as chlorambucil), and antibiotic substances (such as actinomycin D). Fortunately the conditions for which these particular agents may be indicated are generally unlikely to be associated with pregnancy. Other substances questionably implicated include oral hypoglycaemic agents and adrenocortical hormones. The evidence here is equivocal, and, though some reports link their use with the appearance of foetal abnormalities, the suspicions aroused have not been clearly confirmed.

All these and many other drugs are known to be teratogenic in laboratory animals, usually when given in high doses. The list of such drugs is at first sight alarming, including aspirin, penicillin, streptomycin, sulphonamides, caffeine, and nicotine. "In fact the number of agents shown to be teratogenic in experimental animals is so great that the question arises as to whether all agents might not be teratogenic if applied at the critical time in the appropriate dosage in the right species."[1] Despite the earlier deficiencies in testing for teratogenicity before use in therapy, for none of the compounds in the above list has there been any evidence of such effects in man. "Sometimes we forget that drugs have always been tested for their effect on mammalian development . . . by administering them not to pregnant rodents but to pregnant women."[2]

The acknowledgement that additional tests were needed in animals has only sharpened the realization that the safety of any drug is only as great as it is demonstrated to be in man, and that the use of any new drug must continue to be a most cautiously conducted experiment, particularly in early pregnancy.

Placental Barrier

Apart from truly teratogenic effects, almost any drug given for an effect on the mother during pregnancy may have some effect on the foetus. As A. K. Done[3] has said, "From the pharmacological point of view the 'placental barrier' is largely a myth." The placental barrier may give some protection from effects of drugs taken by the mother, but it is safer to assume that even drugs which are non-lipid-soluble and ionized at tissue *p*H, or whose molecular weight exceeds 600, may be transferred across the placenta. Though such transfer is less likely to occur with these drugs than with those of smaller molecular size and greater lipid-solubility, it is known that red cells may be transferred, and there is the additional factor that the tissues of the foetus may be less able (qualitatively or quantitatively) to handle drugs than those of the mother. Thus even for poorly transferred substances an effective concentration of the drug or a metabolite may be achieved in the foetus. Moreover, in the presence of toxaemia, particularly, any generalization becomes even less valid. Apart from its peculiar liability to hazard from drugs given to the mother early in pregnancy, the foetus may be exposed to other drugs at any time during pregnancy and some of these may have deleterious effects.

While in normal pregnancy there may usually be little need for drug therapy,[4] there are sometimes indications for treatment of directly related symptoms, as well as of complications, including infection. The continuing treatment of a patient who becomes pregnant while already under care for a disease produces further problems.

For the common "morning sickness" simple psychotherapy —perhaps with an antacid or placebo—will often suffice. When these measures fail, and active treatment is required, antihistamine antiemetics such as meclozine may be prescribed ; in such a case the doctor "should not be deterred on account of any danger to the foetus."[2] Metoclopramide (Maxolon), a recently introduced antiemetic, is not recommended for use in early pregnancy—presumably because it is not yet known to be safe. For the rare instance of hyperemesis one of the phenothiazines may be effective ; no good evidence of toxic effects on the foetus has been recorded, but the possibility of their causing liver damage should be remembered. The temporary use of the common antacids or attention to eating habits will usually deal with heartburn. Constipation in pregnancy should be treated, as in most other circumstances, by alteration of diet or by occasional use of a mildly irritant laxative. A standardized preparation of senna taken at night is suitable. Preparations containing aloes should be avoided, but bisacodyl (Dulcolax), given in a suppository, may be used.

Sedatives, Tranquillizers, and Hypnotics

Of the sedative, tranquillizer, and hypnotic group of drugs phenobarbitone and amylobarbitone appear to have been used successfully for relatively long periods of time without apparent harm to the foetus. If given during labour phenobarbitone may have a persistent depressant effect on the newborn baby. A similar effect may be seen with preparations of chloral hydrate, especially in premature infants whose glucuronic-acid-conjugation mechanism is not fully developed. Given earlier in pregnancy, chloral does not seem to be troublesome, presumably because the mother's detoxication processes are of greater importance in removing the drug. Phenothiazines have not been shown to have toxic effects on the foetus, but their unwanted effects will be no less in the pregnant woman than in the non-pregnant.

Experience with newer sedatives and hypnotics has been shorter as to both their possible advantages and disadvantages during pregnancy. In view of their known side-effects in the adult it is not surprising that the giving of these depressant drugs just before delivery has been sometimes associated with less attentiveness, a longer period of disorganized activity, and slow adaptation to breast feeding in infants. Longer-term effects said to occur in rats have not been reported in man. Meprobamate (Equanil), chlordiazepoxide (Librium), oxazepam (Serenid), and nitrazepam (Mogadon) are in this category, and they should not be used without caution during pregnancy.

Though aspirin in large doses is teratogenic in some other species, no such effects have been attributed to it in man. If given late in pregnancy, salicylates, like coumarin and indanedione anticoagulants, may give rise to hypoprothrombinaemia and foetal or neonatal haemorrhage may occur. Suggestions of ill effects of ethyl alcohol during pregnancy have not been positively confirmed. It is known that alcohol rapidly crosses the placenta, but even its use in obstetric analgesia does not seem to be deleterious.

Infections During Pregnancy

Infections arising during pregnancy require appropriate chemotherapy, but here caution is required. A short-acting sulphonamide—such as sulphadimidine—which may be indicated for the early treatment of urinary infection, commonly due to susceptible strains of *Escherichia coli,* is believed to be safe. The sulphonamides with a longer-lasting effect are to a large extent protein-bound and slowly excreted and are known to be undesirable late in pregancy. They may persist in the newborn baby and lead to severe jaundice and possibly kernicterus. Streptomycin, gentamicin, and other antibiotics known to be toxic to the eighth cranial nerve should be avoided if possible, as there is some evidence that they may cause damage to the labyrinth and auditory nerve in the foetus.

Tetracyclines given during pregnancy are now well known to cause staining of the foetal teeth, and, especially in premature infants, cause a reversible impairment of skeletal growth. The antibiotic forms a chelate-complex with calcium, and the period at risk is therefore from about the middle of pregnancy. Not only is the discoloration of the teeth unsightly and permanent, but there is hypoplasia of the enamel with increased susceptibility to dental caries. This effect is probably possessed to some degree by all the tetracyclines. Alternatives should be used whenever possible in the second half of pregnancy. Like other penicillins, ampicillin is not known to have untoward effects on the foetus and is a suitable alternative when the organism is sensitive.

Of the commonly used antituberculous drugs streptomycin, ethionamide, and prothionamide should be used only when this is essential for the control of the disease. Isoniazid does not appear to cause foetal damage, but the toxic potentiality of *para*-aminosalicylate may show up in both mother and foetus. Clearly the chances of foetal damage have to be weighed against the urgent need to continue treatment of the mother with tuberculosis.

Chemotherapy of other diseases during pregnancy may present some difficulties. Evidence on the relative safety during pregnancy of drugs used in malaria is difficult to find, but the abortifacient action of quinine is overrated and other antimalarials have not been reported to cause foetal defects. Where the appropriate drug may have unpleasant effects on the mother, and also a secondary effect on the foetus, this will favour postponement of therapy until after delivery if the condition is not urgent.[4] A recent case of filariasis in a woman 32 weeks pregnant illustrates this situation, for a possible allergic reaction to diethylcarbamazine was a sufficient contra-indication to its use during the pregnancy.

Drugs for Cardiovascular Disease

It is accepted that if the usual therapeutic doses of digitalis glycosides are used in pregnant women no harm comes to the foetus, in spite of clear evidence that they do penetrate to the foetal heart and brain. Drugs which raise the blood pressure as a result of peripheral vasoconstriction may cause foetal asphyxia owing to constriction of the uterine vessels. This situation might arise, especially during labour. Nevertheless, the foetus does appear to be partially shielded from direct effects of catecholamines by the monoamine oxidase present in the placenta.

In severe hypertension it is not clearly known whether the continued use of hypotensive drugs as "the only alternative to termination"[4] carries any additional risk to the foetus beyond that already known to exist in this disease. Ganglion-blocking drugs may produce definite alterations of autonomic activity in the foetus—notably circulatory and intestinal effects. Babies born to mothers given reserpine within two days of delivery show signs of respiratory obstruction associated with nasal stuffiness, owing to transient effects on the nasal mucous membrane.

Thiazide diuretics, though useful in controlling the effects of pre-eclamptic toxaemia, are not without hazard to the foetus. Foetal death, together with liver damage or pancreatitis in the mother, have been reported. The incidence of thrombocytopenia, possibly due to sensitization of the foetus, is uncertain but probably low.

Unless care is taken, iodide or antithyroid drugs given to a pregnant woman may produce enlargement of the foetal thyroid by an analogous mechanism to that which may occur in the mother. If a hyperthyroid woman becomes pregnant drug treatment should be continued with the minimum necessary dosage, though some doctors believe that surgical operation is justified. Symptoms often decrease later in pregnancy. Progressive reduction in the dose of antithyroid drug should aim at stopping treatment by about one month before delivery. If this can be done the likelihood of goitre in the baby is slight. Radioactive iodine is clearly hazardous, because it will be taken up by the foetal thyroid, causing involution and secondary effects.

Treatment of Diabetes

The pregnant diabetic also requires special consideration. Continued use of oral hypoglycaemic agents has been reported to be associated with foetal death, but good evidence on this point does not appear to be available. Control of dosage is likely to be more difficult, especially with the longer-lasting drugs. Careful control, using insulin in hospital, would appear to be a safe recommendation.

Other hormones, adrenocortical or gonadal, are potentially capable of having effects on the skeletal and sexual characteristics of the foetus and newborn child. Androgens, oestrogens, and progestogens should be avoided in pregnancy. Progestational hormones are not of proved value for the prevention of habitual or threatened abortion. The case against adrenocortical hormones is much less strong and there is no proved causal link between them and the occasional abortion or stillbirth. Although "there is no doubt that women taking a steroid throughout (pregnancy) have both conceived and borne normal babies,"[5] it is wise to avoid high doses, especially in the first trimester.

Drugs Used During or Immediately Before Delivery

Care in the use of drugs is particularly necessary at or near to full-term. The susceptibility of the newborn infant to drugs given to the mother may be adversely affected by several factors—including asphyxia and trauma during birth—as well as deficient mechanisms of detoxification and excretion because of enzymological immaturity and inefficient renal function. F. Moya and V. Thorndike[6] have given a useful comprehensive review of this topic.

The problems associated with the giving of sedatives, analgesics, and anaesthetics to the mother are generally well recognized. The use of morphine and similar substances given for maternal analgesia are known to be sometimes responsible for cyanosis and respiratory depression in the baby. In babies born of addicted mothers pinpoint pupils and withdrawal symptoms have been reported. Pethidine is commonly said to cause less respiratory depression than morphine, but it is probable that respiration in the baby will be at least as depressed as in the mother at the time of birth, whichever analgesic is used.

Other potential dangers arise from the infant's inability to metabolize drugs with efficiency equal to that of the adult. In laboratory animals oxidative pathways appear to be the most deficient at birth, but in newborn children conjugation processes for chloramphenicol, paracetamol, salicylate, and bilirubin have been reported to be less efficient. Toxic effects of chloramphenicol in neonates have been reported even after greatly reduced dosage schedules. It is clearly wise particularly to avoid giving this drug to the mother at this time.

Several drugs may produce an exaggeration of the normal hyperbilirubinaemia of babies if given to the mother just before delivery. The conjugation of bilirubin is already relatively inefficient in the neonate. Hence drugs which use the same conjugation mechanism may cause an increase in the concentration of "free" unconjugated bilirubin. Excess of this can result in brain damage—namely, kernicterus.

Protein-bound Drugs

In addition, drugs which are to a large extent protein-bound may compete with bilirubin for protein-binding sites and thus have a similar effect. Thus, as already mentioned, long-acting sulphonamides given to the mother have been reported to cause hyperbilirubinaemia in the baby. The following drugs have been reported to have high in-vitro activity of this kind—though clinical confirmation is fortunately so far lacking—novobiocin, indomethacin, salicylates, and tolbutamide.

Neonates also have a greatly increased sensitivity to drug-induced methaemoglobinaemia, probably because of deficient enzyme activities in the erythrocyte. Phenacetin, local anaesthetics, nitrites, and sulphonamides are dangerous in this respect. Once again there is little evidence to implicate the administration of these drugs to the mother with toxicity in the baby. Nevertheless, it would be wise to use any of them with understanding caution. Haemorrhage—sometimes fatal in the foetus or baby—after giving anticoagulants (or large doses of salicylates) to the mother has already been referred to. This may arise even when the maternal prothrombin level is not excessively depressed.

This brief review seems to have left few classes of drug available for unquestioned use during pregnancy. The risk of giving a drug to a pregnant woman is not confined to the developing embryo in the first trimester, and (as with all treatment) the decision to prescribe must be taken after a careful assessment of the relevant factors. Each prescription should represent a calculated risk. The continuing uncertainty of the extent to which some drugs can be used in pregnancy with relative safety is mainly caused by a lack of adequate knowledge of the clinical pharmacology of both new and not so new drugs. It still remains true for drugs which are used frequently that "where there is lack of positive information it is suggestive that the drugs concerned are at least of no lasting harm to the foetus when given to the mother in the usual therapeutic doses."[7]

Conclusions

(1) In normal pregancy there is little need for drug therapy.

(2) Prescribe drugs for pregnant women only when there is a clear indication and then for as short a period as possible.

(3) Keep a record of the dosage and timing of all drugs given during pregnancy.

(4) Since pregnancy may occur in any woman of child-bearing age, this possibility should act as an additional restraint on unnecessary prescribing of potentially hazardous drugs.

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Cyclandelate and Cerebral Circulation

Q.—*Is there any evidence that cyclandelate significantly improves cerebral circulation?*

A.—There have been a number of recent reports suggesting that cyclandelate can increase cerebral blood flow. It is difficult to evaluate the results of these studies, because different methods of measuring cerebral circulation have been used in them all.

Eichhorn[1] employed a technique injecting a radioactive isotope intravenously and measuring the cerebral circulation by surface counting over the torcular Herophili. He studied 40 patients with cerebrovascular disease and found that cyclandelate in an oral dose of 800 mg. daily for a period of three weeks significantly raised the blood volume and reduced the pathologically increased circulation time in patients with mild to moderate cerebrovascular insufficiency. Luisada and his colleagues[2] used impedance plethysmography, and demonstrated that cyclandelate in a similar dose caused consistent vasodilatation of the arteries of the skull and brain. Their subjects were 26 elderly inmates of a home for the aged.

Kuhn[3] did angiography with high speed film changing on 25 patients with focal cerebral ischaemia. The first angiograph was done within two weeks of the onset of symptoms and the second 12 weeks later, the patients having been given cyclandelate 400 mg. four times daily over this period. He claims that 19 patients were clinically improved, 11 markedly so, and that the repeat angiographs showed an increased velocity of blood flow.

O'Brien and Veall[4] measured cortical blood flow by the clearance of Xe-133 in nine patients with cerebrovascular disease whose clinical condition was stable. The patients acted as their own controls. Observations were made on two occasions, after a placebo and after an oral dose of 1 g. of cyclandelate. Analysis of the results showed that there was a significant increase in blood flow after cyclandelate.

These results must still be regarded as preliminary observations. The number of patients is small, and, except for O'Brien and Veall's study,[4] the investigations have not been as well controlled as one would wish. None the less, it is suggestive that all the observers using different techniques have demonstrated an increase in cerebral blood flow. If the findings are confirmed it will be of great importance, because none of the other commonly used vasodilator drugs has been shown to have a consistent effect upon the cerebral circulation.[5]

Pain in the Back

Q.—*What is the best answer to give to a woman who wishes to know why she has pain in the back of long duration after it has been explained to her that organic disease has been excluded and no abnormality in the back can be found?*

A.—This all too familiar problem can be answered in two ways. Firstly, assuming that the given facts are completely accurate and that there is no organic cause for the patient's pain, the cause of the pain must be psychogenic. If the psychological causes or stresses are reasonably clear these should be dealt with on conventional lines—reassurance, superficial psychotherapy, and mild sedation. Diazepam 6 mg. daily in divided dosage is often very helpful. A small proportion of women with chronic backache for which no organic or other cause can be found are in fact suffering from a depressive illness with somatic conversion symptoms. The response in two to three weeks to imipramine 25 mg. eight-hourly is often dramatic and revealing.

Secondly, there remains a large group of patients who have backache of a few years' duration, often dating from a pregnancy or minor trauma. Physical and radiological examination reveals no abnormality other than tenderness, either diffuse or local, in the lower lumbar and sacral region. The classification of this type of lesion is a matter of considerable controversy. Thus "sacro-iliac strain," "multifidus triangle syndrome," "chronic lumbar strain," "chronic disc prolapse," "postural back strain"—the list is endless. Because no lesion is directly demonstrable, one pays one's money and takes one's choice, and the choice is wide.

The treatment of choice should be the safest and the cheapest. I would suggest a course of postural and back-strengthening exercises, together with exercises to improve abdominal muscle tone, and, when appropriate, a weight-reducing regimen. The general increase in fitness and well-being induced by a regimen of this type can do only good, and after instruction it can be carried out at home. The very few remaining patients who do not respond to these treatments are best managed by a programme of optimistic support and encouragement.

Notes and Comments

Chilblains.—Professor J. T. INGRAM (Leighton Buzzard, Beds) writes: The information provided by your expert ("Any Questions?" 24 June, p. 818) towards the understanding and management of chilblains might with advantage be expanded. The increased susceptibility of young women and the absence of chilblains in certain climates and where central heating and air-conditioning are effectively employed must be significant. Occupational factors and the importance of posture were emphasized by Winner.[1] It might have been explained that an adequate reaction to ultraviolet irradiation causes prolonged relaxation of the spasm of arterioles in the skin—an important factor in the mechanism—as shown by Holti.[2] The brief reference to clothes might have included praise for the fashion of trousers and tights for women and those decorative, long-legged woollen knickers.

Internal measures are admittedly disappointing in the treatment of chilblains of the legs, but chilblains occur elsewhere and there is still a place for small doses of thyroid for chilblains of the digits.

OUR EXPERT replies: While I am sure Professor Ingram's gallant support for decorative woollen knickers will be appreciated in the right quarters, I must now amplify my remarks on therapy. Discussion of the "mechanism" of action of ultraviolet irradiation would best be postponed until such an action is proved, and in this respect the observations of Holti and Ingram[3] were uncontrolled. Finally, the place for small doses of thyroid in the treatment of digital chilblains is in the clouds of dermatological mythology rather than the rocks of practical therapy.

Book Reviews

Profitable Reading

Clinical Surgery: Abdomen and Rectum and Anus. Edited by Charles Rob, M.C., M.Chir., F.R.C.S., Rodney Smith, M.S., F.R.C.S., and Sir Clifford Naunton Morgan, M.S., F.R.C.S., F.R.C.O.G., F.A.C.S.(Hon.). (Pp. 645+xiii; illustrated. £7 15s., £4 10s. per vol. in complete set.) 1966.

A good book has been defined as one "which is opened with expectation and closed with profit." This is my experience after a complete perusal of this book where forty-one authors give us the present-day look of abdominal and rectal surgery. Graduates are bound to study it in detail and use it for reference work. It enhances the already established reputation of this valuable system of *Clinical Surgery*.

The division of surgery into component parts, historical, clinical, operative, and experimental, creates certain difficulties for editors and authors in deciding where to "draw the line"; what should be excluded in specific texts? In this book the editors' objective is to give a review of the clinical aspects of the subject and of the investigations required in diagnosis; they have achieved this objective in an admirable manner. Some detail and diagrams of operative technique have, however, been included in certain chapters which could be pruned in view of the availability of the appropriate volume of *Operative Surgery*, and the space given to other material. Each author has made good use of the space allotted to him for complete coverage of his subject, and helpful references for further reading are provided. The present position of a number of subjects will not remain static; the authors demonstrate how much surgical research is still required to understand and manage many abdominal affections. For example, we know little about the aetiology of peptic ulceration, gallstones, and pancreatitis, or the role of degeneration in Auerbach's plexus, a common factor in achalasia of the cardia and Hirschprung's disease. It is fortunate for patients with achalasia that Heller's operation is so satisfactory, although the condition carries the risk of many complications, and the association with oesophageal carcinoma must now be stressed. The number of operations performed for Hirschprung's disease and rectal prolapse witnesses to all the treatment problems awaiting solution. For the latter condition recto-sigmoidectomy must now pass into history. The author calls attention to the experimental evidence for the carcinogenicity of buried thick Ivalon sheets. Mention should be made of the value of perineorrhaphy and sphincter reconstruction for rectal prolapse with anal incontinence.

Although the aetiology of peptic ulceration in the stomach and duodenum still eludes us, the surgical treatment required has been clarified with emphasis on the value of Billroth I gastrectomy for a chronic gastric ulcer and selective vagotomy with a drainage operation for a chronic duodenal ulcer. The treatment of a chronic gastric ulcer is really a surgical problem, for confusion with a carcinoma is not uncommon, and is it wise to leave the ulcer by performing vagotomy and pyloroplasty? The mortality and relapse-rate following present operations for perforated peptic ulcers are still too high; perhaps vagotomy with suture of perforated duodenal ulcers will improve this position. Surgery is wisely advised for asymptomatic cholecystitis and cholelithiasis in the absence of a contraindication, and the patient has a life expectancy of up to 15 years. The arguments are summarized for the surgical or conservative treatment of acute cholecystitis; but I wanted to know the author's opinion! The physiology and clinical evaluation of abdominal pain is helpfully considered and good advice given on abdominal emergencies with a full description of radiology of the acute abdomen. Cancer of the stomach remains a frequent and dangerous tumour, although a little gloom has been dispersed by radical surgery, but this is not entirely satisfactory, for too many patients have lymph node metastases, with consequently a poor prognosis, when this is done. We must now make progress with preventive treatment and early detection methods using newer screening techniques, including cytology and gastrophotography as well as radiology.

A number of useful investigations in abdominal surgery are described, including those relating to the liver. The relationship of the liver with so many abdominal lesions enhances the importance of such studies, including biopsy. The value of the latter when cholecystectomy is done might be mentioned, for sometimes unsuspected biliary cirrhosis is thereby discovered. The rectum and anus have received full attention, including excellent coverage of cancer in these organs, but why is such an important subject as cancer of the colon omitted, except in connexion with intestinal obstruction? Other notable omissions in the book are colonic diverticular disease and ulcerative colitis; both are attracting considerable attention today. It was pleasurable to read Sir Zachary Cope's account of abdominal actinomycosis. Fortunately this is rare in our country today.

I would like to review each chapter, but this is impossible for lack of space; each author has made a valuable contribution and the editors have welded them into a very readable book. This volume deserves to be widely studied.

RONALD W. RAVEN.

Flood of Patients

Psychiatric Illness in General Practice. By Michael Shepherd, Brian Cooper, A. C. Brown, and G. W. Kalton. (Pp. 220+xvii. 45s.) London, New York, and Toronto: Oxford University Press. 1966.

It is generally accepted that a large proportion of medical illness is functional rather than organic. The figures vary considerably, from less than 4% to over 60%, and it is obvious that the populations, or the investigators, or the criteria differ. What is common to most of the published work is that the writers base their opinions on conjecture and clinical impressions, which are notoriously misleading. In this, as in other psychiatric fields, there is a plethora of speculation and a paucity of data.

This book is an attempt to provide data, but it is more concerned with methods than results. It can be divided into three main parts—firstly, a review of the existing state of knowledge in this field; secondly, a description of the methods of investigation; and thirdly, the results.

Briefly, a random sample of the patients seen by 76 doctors in 46 practices was analysed over a period of a year. The results suggest that about 14% of patients seen in general practice are suffering mainly from psychiatric disorders in a proportion of two women to one man. The majority of these are minor cases and only 4% were psychotic. There was, however, considerable variation between individual doctors' reporting. It is also of interest that only about one-tenth of the cases were referred to psychiatrists, and this survey suggests that the reservoir of cases is such that ten times as many patients could be referred to psychiatrists as are at present. If such patients were referred, the psychiatric services would break down, and it is obvious that general practitioners must continue to carry the main burden of psychiatric care even though the treatment of minor psychiatric disorders in general practice is often inadequate and haphazard. The authors conclude that the cardial requirement for the improvement of the mental health services is not an expansion of the psychiatric agencies but a strengthening of the family doctor. This is a process which must start in the medical school, followed by a reduced patient load in general practice and better ancillary services.

This book is of value to general practitioners and sociologists and also to psychiatrists, who may become more sympathetic to the problems of their colleagues in general practice—and grateful to them for the flood of patients they are keeping away.

A. W. BEARD.

Neuroanatomy

The Essentials of Neuroanatomy. By G. A. G. Mitchell. (Pp. 111; illustrated. 15s.) Edinburgh and London: E. & S. Livingstone. 1966.

This modest little volume makes more generally available Professor Mitchell's introduction to the study of the central nervous system, which first appeared as a private publication some sixteen years ago. As is to be expected from the author, it is a completely reliable account of many of the essentials of neuroanatomy and will doubtless provide help to students entering upon the study of the structure of the human nervous system. It is a pity that the opportunity provided by the reproduction of the little volume was not exploited to include some of the considerable developments in our basic knowledge of the structure of the nervous system established in the past few years. In particular some reference to the very considerable contributions to this knowledge made by electron microscopy could have been intercalated to advantage. Indeed, the structure of the nerve fibre itself, and the important relationships between nerve cells and glial elements in the central nervous system, can be reasonably presented only in the light of ultrastructural observations. In the reviewer's opinion some reference to the results of the application of histochemistry to the study of nervous tissues would have been stimulating, showing, as they can, the links between anatomy on the one hand and physiology and biochemistry on the other. An analysis of the nerve supply to a muscle and more detailed accounts of fibres of different calibre in the spinal nerves could also have been expected, and would be helpful to the neophyte. But these are perhaps suggestions for the next edition of this introductory volume; they are not meant to be carping criticisms of a useful book.

J. D. BOYD.

Working and Reproduction of a Cell

Growth, Function, and Regulation in Bacterial Cells. By A. C. R. Dean and Sir Cyril Hinshelwood. (Pp. 439+xii; illustrated. 84s.) London: Clarendon Press. Oxford University Press. 1966.

Despite its title, this book has little in common with others on the subject, and the reader expecting a balanced discussion of chromosomal replication, enzyme induction, and the like will be sadly disappointed. This is a highly idiosyncratic statement of a general model for cell growth and metabolism, accompanied by experimental results similar to those of Hinshelwood's *Chemical Kinetics of the Bacterial Cell* (1946).[1] The heart of the model is the principle of "total integration" which states that the "working and reproduction of a cell demands the harmonious gearing of all its parts." This finds formal expression in the "network theorem" which presupposes that the "growth of living matter depends upon closed cycles of mutually dependent interactions" and yields general relations involving quantities like cell numbers or duration of lag but not specific macromolecules or enzyme pathways.

Considering the model in isolation, most readers would probably agree that cells might conceivably work in this way. Doubts immediately arise from one of the main assumptions—that each cell component increases exponentially as time passes. This can be true for populations of asynchronously dividing cells but is certainly untrue of an individual cell, the subject of the model, in which the number of copies of a given gene or the amount of a given enzyme is known to double abruptly during the growth cycle. On the face of it, assumption and observation appear irreconcilable.

Apart from questions of detail, the principle of total integration leads to a considerable difficulty. While most workers would probably regard the principle almost as a truism, they also believe that integration is not so complete that the study of single enzyme systems or other isolated phenomena is likely to yield meaningless results. The authors, on the other hand, appear to hold that current interpretations of such experiments may well be fallacious because, if integration is indeed "total," then any change in conditions necessarily alters the cell as a whole, so that any response may be due to processes other than that which the experimenter believes he is studying. Thus, any conventional explanation can be countered by a hypothetical alternative justified by the principle. The difficulty of this position is that, granted cells to be complex, the counter hypotheses may be correspondingly complex and hence untestable. There is one notable exception. Certain instances of drug resistance are ascribed to purely non-genetic events, but genetic change has not been excluded by using any of the well-known methods of gene transfer in bacteria.

The authors' model may or may not be correct, but until it is tested more directly it seems unlikely to shift modern biology from its present course.

G. G. MEYNELL.

Textbook of Bacteriology

An Outline of Bacteriology and Immunity. 3rd edition. By Ronald Hare, M.D. (Pp. 472+xii; illustrated. 50s.) London: Longmans. 1967.

The interval between editions of this book has been reduced from seven to four years, a clear indication of growing popularity. The principal change in this edition is an expansion of the section on viruses, the previous single chapter being subdivided into no fewer than nine on a generic basis; that on adenoviruses occupies only one page and some others only two. Might not some of the chapters on bacteria benefit from similar if perhaps less drastic treatment? That on Gram-negative bacilli embraces 15 genera, and even so seems less heterogeneous than its Gram-positive counterpart, which includes the *Mycobacteria*, surely distinctive and important enough to deserve a place of their own, and *Bacteroides*, most of which are in fact unequivocally Gram-negative. *Listeria* and *Erysipelothrix*, which might also have been included, appear in a chapter on filamentous organisms, in which there is also a new description of *Mycoplasma*. Infectious drug resistance is now briefly described, but in this connexion the statement that "ampicillin is the drug of choice" for treating *Salmonella* infections must be contested. This drug is still chloramphenicol, and the main apprehension in connexion with transferable resistance relates to it.

This is a most attractive book, profusely and beautifully illustrated and dealing admirably with principles and the general aspects of its subject—immunity and epidemiology in its widest sense. The largest and perhaps best chapter, on the sources and transmission of infection, embodies much of the author's own original work, and can be read with profit by anyone. In contrast to these the few chapters describing individual bacteria seem in places rather terse and elementary and might fail to provide the more interested student with all the information for which he hopes. In an ever more crowded curriculum the teaching of practical bacteriology may have to be curtailed, but a real and abiding interest in the subject can come only from first-hand bench experience. It is to be hoped that a trend to more theoretical teaching will not deprive the profession of bacteriology of its future recruits.

L. P. GARROD.

Recent Work in Paediatrics

Advances in Pediatrics. Vol. 14. Edited by S. Z. Levine. (Pp. 307. 87s.) London: Lloyd-Luke. 1966.

The fourteenth volume in this series contains the customary six monographs. The subjects covered are: ulcerative colitis, poisonings, haemoglobinopathies, attenuated live virus vaccines, hereditary renal glomerular diseases, and physiological and biochemical determinants of development.

Two of these articles are of practical importance to family doctors as well as to paediatricians. "Poisonings," contributed by the late Dr. H. Jacobziner, Assistant Commissioner, Department of Health, New York, is an excellent exposition, starting with an epidemiological survey, continuing with the commonest specific poisonings, their clinical aspects and treatment, and concluding with control and preventive measures. Particularly important are the nine main contributory factors which he enumerates, and his timely warning that "the universal antidote is neither universal nor specific." The second "practical" article is on the current status of live attenuated virus vaccines by Drs. D. T. Karzon and D. A. Henderson, from New York and Atlanta respectively. This is the longest contribution, occupying 79 pages. Consideration is given to smallpox, rabies, poliomyelitis, measles, yellow fever, and rubella. The information is up to date and includes the use of intradermal injections by jet, the best technique available today.

Three of the articles will appeal particularly to the specialist: those on ulcerative colitis, the haemoglobinopathies, and determinants of development. The first, by Drs. O. Brobergen and R. Lagercrantz, of Stockholm, is an excellent account of the condition, and stress is rightly laid on the extracolonic and systemic manifestations. This article will also be of interest to surgeons. There is an addendum to this chapter which brings the report up to 1966. Erythema nodosum is cited as one of the extracolonic signs and is noted in the index, where the reader is advised to "see under skin conditions"; but unfortunately there is no such heading in the index. The second contribution is from Professor J. H. P. Jonxis, of Groningen, an acknowledged expert in the field of abnormal haemoglobins, and he has given a masterly account; his references even include two from *Nature* in 1966. The third of these articles is a scholarly exposition of recent discoveries in biochemical genetics by Drs. N. Kretchmer and R. E. Greenberg, of California.

The last article is by Drs. W. W. McCrory, M. Shibuya, and H. G. Worthen, of New York, on hereditary renal glomerular diseases. Here are considered chronic glomerulonephritis, nephrosis, nephronophthisis, and Fabry's disease. This is an extremely interesting chapter.

The standard of production of the book achieves the same level as its predecessors, and once again Dr. Levine is to be congratulated on his selection of authors. One of the features is the bibliography supplied by all the writers, more than 900 references being quoted. There are nine plates, nine tables, and 27 figures and there are both author and subject indexes.

WILFRID GAISFORD.

Plants in Pharmacology

Plant Drugs that Changed the World. By Norman Taylor. (Pp. 275+viii. 30s.) London: Allen & Unwin. 1966.

The author of this book is described on the dust-cover as "one of the outstanding authorities in the English-speaking world on plants and flowers. . . ." He has here applied his extensive knowledge to writing a series of essays on the historical background and the economic significance of a number of drugs that are derived from plants. *Plant Drugs that Changed the World*—as becomes a book with such a resounding title—makes interesting reading, but the author falls between two stools. His material is rather too technical for readers other than botanists, pharmacists, and physicians; on the other hand, the literary style—approximating to that of the popular press—will often exasperate the serious student.

Nevertheless, Mr. Taylor shows considerable skill in combining a popular presentation of pharmacology with thumbnail biography. Readers on Tyneside will be surprised to learn that Dr. Thomas Addison, of Guy's, was "a Scottish physician." There is a useful bibliography.

STANLEY ALSTEAD.

Nutrition Review

World Review of Nutrition and Dietetics. Vol. 7. Edited by Geoffrey H. Bourne. (Pp. 255+viii. £7.) London: Pitman. 1967.

The seventh volume in this useful series justifies its global title by including three contributions from the U.S.A., and one each from Canada, England, Holland, and Scotland. L. Cesal, L. Blakeslee, and E. O. Heady, of Iowa, have written the first article on "The World Food Situation." On the maximum basis of a rapid increase in population, combined with greatly improved nutrition, A.D. 2000 may see the world's population more than doubled, and the requirements of animal protein more than trebled. To all but the middle-aged the prospect must be alarming. The authors' final words that the "world food situation will be a subject for close scrutiny from many points of view in the years to come" seem an understatement. S. E. Johnson, of the U.S. Department of Agriculture, deals with "Economic Implications of Food Aid." The supply of free food to a backward country may sometimes help economic development, by giving the inhabitants the bodily strength necessary to get on with their own agricultural activities, or may sometimes hinder, by making the inhabitants complacent and lazy. As in many documents discussing international relationships the verbiage in this article is expansive rather than simple. For example, "food aid" is equated with the food itself as a thing which needs to be transported and stored.

M. C. Latham, of Boston, U.S.A., assisted by F. J. Stare, reports on "Nutritional Studies in Tanzania." The great diversity in both the ecology and the inhabitants in this large country makes it difficult to generalize about either the diet or the nutritional status. Protein-calorie deficiency, nutritional anaemias, vitamin-A deficiency, and ariboflavinosis occur in many areas. The possible danger of liver disease arising from the consumption of groundnuts contaminated with *Aspergillus flavus* urgently requires investigation. A. B. Morrison and M. N. Rao, of Ottawa, discuss "Some Relationships Between Proteins and Calories," emphasizing the point that protein cannot be used efficiently when the diet is deficient in calories. G. A. Garton, of Aberdeen, reviews "The Digestion and Absorption of Lipids in Ruminant Animals," mentioning that some minor components among the fatty acids in foods of animal origin, such as butter, originate in microbial synthesis in the rumen.

For the rest about half the space in this volume is taken up by two long contributions which will appeal especially to dental readers. L. M. Dalderup, of Wagenigen, citing about 500 references, has written on "Nutrition and Caries." The presence in the diet of sugar, or of other forms of refined carbohydrates, tends to produce caries, whereas dietary fluoride protects. Besides the carbohydrate content of the diet its consistency (stickiness) is an important cariogenic factor, as also is the habit of eating at too frequent intervals. G. N. Jenkins, of Newcastle upon Tyne, discusses "Fluoride," with the citation of about 200 references. He endorses the fluoridation of water supplies as a public health measure. In wishing success to this series, which deserves inclusion in all libraries concerned with medicine, nutrition, or food processing, we may hope for a return of the photographic illustrations which are an attractive feature in some of the earlier volumes.

T. MOORE.

Books Received

Review is not precluded by notice here of books recently received.

Play and the Sick Child. By Eva Noble. (Pp. 165; illustrated. 22s. 6d.) London: Faber & Faber. 1967.

Planning Guide for Radiologic Installations. 2nd. edition. Edited by Wendell G. Scott. (Pp. 297+xiv; illustrated. 76s.) Edinburgh and London: E. & S. Livingstone. 1967.

Gruppenpsychotherapie in Klinik und Praxis. Edited by Dr. Kurt Höck. (Pp. 224. £1 7s. 7d.) Jena: Gustav Fischer. 1967.

Die Klinische Anwendung der Strahlen in der Heilkunde. By Professor Ivan Kövesligethy. (Pp. 168; illustrated. 180 Austrian marks.) Vienna: Wilhelm Maudrich. 1967.

Lehbuch der Gerichtlichen Medizin. Für Mediziner und Juristen. Edited by Professor Albert Ponsold. (Pp. 645+xii; illustrated. D.M.89.) Stuttgart: Georg Thieme. 1967.

Lehrbuch der Tropenkrankheiten. Edited by Professor E. G. Nauck. (Pp. 471+xi; illustrated. D.M.69.) Stuttgart: Georg Thieme. 1967.

Nierenkrankheiten. By Dr. Hans Sarre. (Pp. 551+xv; illustrated. DM.90.) Stuttgart: Georg Thieme. 1967.

Advances in Ophthalmology. Vol. 18. Edited by M. J. Roper-Hall, H. Sautter, and E. B. Streiff. (Pp. 248; illustrated. sFr./DM.68.) New York and Basel: S. Karger. 1967.

The Predicament of the Family. A Psycho-Analytical Symposium. Edited by Peter Lomas. (Pp. 219. 36s.) London: Hogarth Press. 1967.

Handbook of Paediatrics. 7th edition. By Henry K. Silver, M.D., C. Henry Kempe, M. D., and Henry B. Bruyn, M.D. (Pp. 648. 42s.) Oxford: Blackwell. 1967.

Sans Everything. A Case to Answer. Presented by Barbara Robb on behalf of AEGIS. Pp. 148+xvi. 18s.) London: Thomas Nelson. 1967.

Lyle and Jackson's. Practical Orthoptics in the Treatment of Squint. (And Other Anomalies of Binocular Vision). 5th edition. By T. Keith Lyle and Kenneth C. Wybar. (Pp. 636+xvi; illustrated. £6 6s.) London: H. K. Lewis. 1967.

The Feminine Mind and Body. The Psychosexual and Psychosomatic Reactions of Women. By J. Dudley Chapman, D.O. (Pp. 325. 60s.) London: Vision Press. 1967.

Documentary History of Psychiatry. A Source Book on Historical Principles. By Charles E. Goshen, M.D. (Pp. 904+x. 84s.) London: Vision Press. 1967.

A Manual of Closed Reduction of Closed Fractures and Dislocations. By Robert Mazet, jun., M.D. (Pp. 131+ix; illustrated. $10.50.) Springfield, Illinois: Charles C. Thomas. 1967.

Introduction to Scientific Psychiatry. A Behavioristic Approach to Diagnosis and Treatment. By H. A. Storrow, M.D. (Pp. 256+xvii. $6.95.) New York: Appleton-Century-Crofts. 1967.

Middle Articles

British Medical Association

Annual Scientific Meeting, Bristol, 10-14 July

The Association's 135th Annual Meeting was held in Bristol from 6 to 14 July. The Annual Scientific Meeting was held in the University Students' Union building from 10 to 14 July. The programme comprised symposia on the Management of Breast Carcinoma, Prescribing and Adverse Reactions to Drugs, Problems of Accident and Emergency Services, Diarrhoea, and Cardiac Emergencies; Modern Trends lectures on Shoulder Pain, Resuscitation in the Newborn, Diabetes—the Present Situation, Cytotoxic Drugs in the Treatment of Malignant Disease, the Natural History of Enuresis, Urinary Incontinence in the Aged, and Rheumatoid Arthritis—Conservative and Surgical Management; Panel Discussions on Vocational Training for General Practice, Bereavement, the Place of Surgery in Acquired Cardiac Disease, Headache, On Withholding Antibiotics, and Maternity Service; and Plenary Sessions on Diagnostic Pitfalls in General Practice—the Abdomen, and Recreation. In addition there was a programme of medical films, and the customary Scientific Exhibition and the Annual Exhibition of Pharmaceutical Products, Instruments, Appliances and Medical Publications were all held in the same building. A report of the scientific sessions is given below and will be concluded next week.

Management of Breast Carcinoma

Monday, 10 July

The symposium on the management of carcinoma of the breast, with Professor Sir HEDLEY ATKINS (P.R.C.S.) in the chair, was opened by Sir STANFORD CADE (Westminster Hospital, London), who discussed the relative value of different forms of treatment. Sir Stanford emphasized that choice of management should depend on clinical and pathological assessment rather than on the philosophy of the clinician. When assessing five-year survival rates it should be remembered that the average survival without treatment at all was three years and eight months. The response to treatment depended on the biological type of the tumour, which could be graded histologically. The stage at which the cancer was seen was not an indication of its malignancy. Reviewing the 4,000 cases of breast cancer he had seen in the last half-century, Sir Stanford had concluded that surgery was the most effective form of treatment and had applications in each stage. However, of 20,000 patients dying annually of breast cancer only 6,000 could benefit from surgery, whereas three times as many could benefit from radiotherapy. Furthermore, the results of radiotherapy were still improving, whereas those of surgery were not. Hormone therapy had been shown to control breast cancer, and ablation of endocrine glands often gave longer remissions than administration of hormones; but this was unpredictable. Chemotherapy was the treatment of last resort. It had never cured patients with this condition, and the least toxic agents were the least effective. The use of 5-fluorouracil intra-arterially was perhaps the most promising method.

Radiotherapy

Professor Sir BRIAN WINDEYER (Middlesex Hospital) presented the radiotherapist's point of view. There were now many radiotherapeutic techniques available for the many presentations and situations arising in breast carcinoma. Results of five-year and 20-year survival studies, respectively 12% and 6% in 1934–5, had improved to 31% and 16% in 1950–4, and to 34% five-year survival in 1955–8. These figures reflected increasing clinical skill and experience and technical advances, but still did not draw attention to the social importance of improved palliative treatment. In outlining his current policy for each stage, Sir Brian emphasized that postoperative radiotherapy had not improved the results of radical mastectomy in stage 1 carcinoma. However, radiotherapy was applicable if examination of the internal mammary or apical axillary lymph glands showed tumour cells.

In stage 2 cases the ideal plan was to take a biopsy of the internal mammary glands in the upper two intercostal spaces before deciding between surgery and radiotherapy. It was usual to give radiotherapy prior to biopsy. This did not affect the histological appearances, but there was no evidence to show that the chances of dissemination were reduced. Finally, radiotherapy was the sheet anchor of treatment for individual metastases.

Hypophysectomy

Mr. J. ANGELL JAMES (Bristol) discussed the role of hypophysectomy in the management of carcinoma of the breast. This operation had proved better in producing remissions than combined oophorectomy and adrenalectomy, probably because other active hormones such as growth hormone and prolactin were also removed. It was important to do the operation as soon as it was clear that other forms of treatment had not been successful, as the chances of success diminished as the patient's condition deteriorated. The best results had been obtained in patients aged between 60 and 70, with deposits in bone, skin, and lymph glands. Chest, brain, and liver metastases had proved less responsive. The transethmosphenoidal operation had the advantages of short operating time, good vision with an operating microscope, minimal pain, and rapid convalescence. It was contraindicated in the presence of nasal or sinus infection. Leakage of cerebrospinal fluid could now be prevented. Some degree of diabetes insipidus always occurred but was easily controlled, and a watch had to be kept for early signs of myxoedema. In a personal series of 326 cases Mr. Angell James reported an operative mortality of 1.3%. Only 7.2% had died in the first three weeks (5.9% died of advanced cancer), and remissions at one month had been 64%, at six months 29%, at 12 months 17%, and at five years 1%. Pain had usually been relieved in 24 hours, and many bedridden patients had been remobilized.

General Practitioner's View

Dr. I. R. MCWHINNEY (Stratford-on-Avon) gave the general practitioner's point of view. He emphasized the personal co-operation needed between surgeon, radiotherapist, and family doctor to obtain not only the best technical results but also the best emotional and social result for the individual patient. The tumour could be palpable before the patient noticed it, and practitioners should take every opportunity of examining breasts. Patients sometimes concealed their tumours for months. When a breast lump was found, Dr. McWhinney's practice was to explain the likely diagnosis and treatment to the patient without evasion, and to obtain surgical consultation as soon as possible to relieve anxiety as much as to arrest the tumour. Later he made sure that the best prosthesis was offered to the patient if mastectomy was performed. Dr. McWhinney was opposed to automatic long-term follow-up in uncomplicated patients except for definite research purposes, and felt that regular careful examination and attention to complaints by the general practitioner gave better clinical and social results than intermittent follow-up by a series of doctors at the surgical clinic.

This last point excited considerable discussion. Sir HEDLEY ATKINS thought that it should not be left to the patient to report merely when she had new symptoms, and that, for example, any pain in the back should be treated as metastatic irrespective of the radiological appearance of the spine. Sir BRIAN WINDEYER said that asking specific questions would elicit evidence of metastasis earlier.

Shoulder Pain

The modern trends lecture on "Shoulder Pain," under the chairmanship of Dr. F. S. COOKSEY (King's College Hospital, London), was devoted to both medical and surgical aspects of the problem. Speaking from the physician's viewpoint, Dr. FRANCIS T. PAGE (Bristol) emphasized the importance of differentiating shoulder pain of local musculoskeletal origin, which was aggravated by movement, from that due to brachial neuritis, which was usually unaffected by movement of the shoulder. Although brachial neuritis due to disc lesions or cervical spondylitis was the commonest "medical" cause of shoulder pain, the presence of radiographic abnormalities in the cervical spine did not necessarily mean that these were responsible for the patient's symptoms. Other criteria were therefore required. Neuritic pain was likely to radiate down the arm, was often sharply worse on coughing, sneezing, and straining, and could be brought on by downwards pressure of the head towards the affected side. There was a tendency for brachial neuritis to settle down spontaneously, and it was best treated by analgesics, a simple collar, and a sling to take the weight of the arm off the shoulder. Physiotherapy was not indicated.

Shoulder Girdle Syndrome

Turning to other nonsurgical causes of shoulder pain, Dr. Page described the shoulder girdle syndrome (myalgic amyotrophy), thought to be due to a neurotropic virus infection, and frozen shoulder, which was common after injury and in those confined to bed. Sometimes frozen shoulder had no apparent cause, but most resolved slowly. Physiotherapy had little place in treatment, since manipulation could be harmful, and less strenuous measures did little good. Polymyalgia rheumatica, malignant disease, the carpal tunnel syndrome, angina, and myocardial infarction were further possible causes of pain in the shoulder region.

Degenerative Lesions

Mr. A. L. EYRE-BROOK (Bristol) described traumatic and degenerative lesions of the shoulder joint and outlined the indications for surgical treatment. Rupture of the rotator cuff—a common cause of shoulder pain—could be either traumatic or pathological in origin. The former was curable by operation, but pathological rupture was due to degenerative changes and was not usually amenable to surgery. Degenerative lesions of the shoulder joint were sometimes associated with calcification, which in the case of "Codman's shoulder" extended through the rotator cuff and ruptured into the subdeltoid bursa. These calcified lesions limited movement and required surgical removal.

Frozen shoulder could be associated with changes in the rotator cuff, said Mr. Eyre-Brook, who then outlined the characteristic features—progressively restricted movement, and pain both in the joint and over the deltoid insertion. The patient experienced pain when he lowered the arm, but this did not occur when the doctor lowered it passively. Suspected rupture of the rotator cuff could be confirmed by intra-articular injection of radio-opaque dye, which would escape through the rupture when the joint was manipulated. Mr. Eyre-Brook concluded by describing some other surgical causes of shoulder pain. These included posterior dislocation, which sometimes occurred during fits and was easily missed, osteoarthritis of the acromio-clavicular joint, neoplasms, haemoglobinopathies, and caisson disease.

In the discussion Dr. G. D. KERSLEY (Bath) was in favour of manipulation of the neck for cervical spondylitis in the treatment of brachial neuritis, and other speakers also supported active measures in the treatment of this condition and frozen shoulder.

Resuscitation in the Newborn

Opening a modern trends discussion on resuscitation in the newborn, with Professor N. R. BUTLER (Bristol) in the chair, Dr. G. JACKSON REES (Liverpool) explained how advances in knowledge of the respiratory physiology had led to the development of scientific methods of resuscitation for infants born in apnoea. Early in intrauterine life rhythmic respiratory movements occurred. Later they stopped until a stimulus, such as cold cutaneous stimulation or clamping of the umbilical cord, reactivated them. At birth the newborn baby had to adapt its respiratory and cardiovascular physiology to extra-uterine life within a matter of minutes. If the infant failed to breathe within four minutes of birth brain damage would occur.

In resuscitation it was essential to maintain an effective circulation as well as to induce respiratory movements. Studies on asphyxiated newborn monkeys had shown that acidosis inhibited rhythmic respiratory activity. Resuscitation should be started as soon as possible if the infant did not breathe, as asphyxia led to a rise in the levels of lactic and pyruvic acids, which in turn further depressed respiration. Brain damage was less likely to occur in the asphyxiated newborn infant if the acidosis was treated with an alkali and fructose or glucose, which should be given in addition to ventilation with oxygen and external cardiac massage. Cooling the infant did not increase its chance of survival, and respiratory stimulants were usually useless. Dr. Rees said that he had found artificial ventilation by intermittent positive pressure to be more effective in resuscitating the newborn than the use of hyperbaric oxygen.

Role of Acidosis

Dr. BERYL D. CORNER (Bristol) said that of 11,000 deliveries in Bristol only 4% of the newborn infants had needed active resuscitation. The incidence of neonatal asphyxia was much greater in premature infants (13.6%). Permanent brain damage, with lesions in the brain stem and thalamus, could occur in newborn animals if asphyxia lasted for more than seven minutes. Intraventricular and subdural haemorrhage and thrombosis were frequently seen in asphyxiated premature infants, owing to changes in cerebral blood flow. Acidosis, due to a rise in the levels of pyruvic and lactic acids and in Pco_2, damaged cell membranes. This damage impaired the action of the "sodium pump" and led to retention of sodium and the escape of potassium, so producing oedema of the brain cells.

The acidosis could be treated by infusing 5% sodium bicarbonate solution and 20% fructose solution into the umbilical vein. Dr. Corner confirmed the observation of Dr. Rees that cooling increased the oxygen requirements of newborn infants, whose reaction to environmental temperatures differed from that of adults.

Long-term Follow-up

A long-term follow-up of infants severely asphyxiated at birth showed that brain damage was seldom permanent if active treatment in the form of intermittent positive-pressure respiration and alkali-fructose infusions were given. Of 88 asphyxiated infants followed up over a period of six years only two had developed severe abnormalities. One child had a left spastic hemiplegia and was prone to fits, another was severely deaf, and three had speech defects. Electroencephalography had shown normal patterns in 35 out of 38 children tested.

In reply to a question by Professor BUTLER Dr. REES said that in domiciliary practice resuscitation could be carried out by mouth-to-nose ventilation. Dr. CORNER pointed out that this introduced the risk of infection and pneumothorax. Asked by Dr. G. M. J. SLOT (London) whether midwives should be taught to intubate newborn infants, Dr. CORNER considered this unnecessary, as in domiciliary work asphyxiated babies were rare. Dr. REES doubted whether holding newborn babies up by their feet was of any value in resuscitation.

Prescribing and Adverse Reactions to Drugs

Tuesday, 11 July

The symposium on "Prescribing and Adverse Reactions to Drugs," under the chairmanship of Professor D. R. LAURENCE (University College Hospital), opened with a survey of the work of the Adverse Reactions Subcommittee of the Dunlop Committee, given by its chairman, Professor L. J. WITTS (Oxford). Professor Witts said that his subcommittee's duty was to maintain surveillance over the adverse reactions of drugs already on the market. For this purpose early warning (yellow) cards had been issued for the reporting of all adverse reactions to newly introduced drugs and new or severe reactions to those already established. Over half the yellow cards received came from general practitioners and just over a quarter from hospitals. Information about side-effects was also obtained from death certificates, letters, and published work. Despite this many adverse reactions still went unreported, and in particular there was a tendency not to report reactions familiar to the doctor. Where a patient received several drugs concurrently or had several types of reaction it was important to report all of these, and the system used could record up to five different drugs and five adverse reactions for each patient. About 10% of patients were followed up by personal visits, which had confirmed the reliability of the reports received.

Professor Witts went on to emphasize that the Adverse Reactions Subcommittee intended to use the reports received—and the results of research work in collaboration with other bodies—as more than a statistical repository by feeding back information to prescribers. He concluded by repeating that there were difficulties in precisely defining adverse reactions, and there was still a need for more yellow cards to be sent in.

MacGregor Classification

Developing the theme that responsibility for prescribing rested with the prescriber, Professor A. G. MACGREGOR (University of Aberdeen) said that the empirical approach had done little harm in the past, when most medications had been ineffective and relatively innocuous. With more effective modern drugs there was a need for more precise evaluation, and this was emphasized by estimates that between 10% and 15% of bed occupancy was accounted for by iatrogenic disease. Professor MacGregor continued by outlining the categories of the MacGregor classification, which was designed to help prescribers recognize preparations which were the subject of monographs in the *B.P.*, *B.P.C.*, or *B.N.F.* (category M) or were acceptable alternatives or combinations of drugs (category A). Drugs assigned to category B were considered less effective or more toxic than those in the other categories, or their efficacy was unproved. Some drug combinations were also considered inappropriate. Evaluation of the action of drugs and their side-effects was hindered by several factors, among them the discrepancy (20% in studies from Belfast and Aberdeen) between what the doctor prescribed and what the patient actually took. Concluding, Professor MacGregor stressed the importance of supplying prescribers with adequate information on which to base their decisions.

Teaching Students

Dr. J. E. CATES (Bristol) said that students now learned about existing knowledge of drug side-effects before they began their clinical training. It was important for consultants to build on this theoretical knowledge by teaching on patients in whom ill effects had actually developed, so that students would learn at first hand about the management of the problems created. When patients developed a complication, however minor, the consultant should first check the prescription card for possible causes of the upset. Students should be taught always to warn patients of the possible ill effects of drug treatment. By seeing or taking part in clinical trials students could see something of statistical methods and the placebo effect, as well as adverse reactions. From adverse reactions Dr. Cates turned to the basic principle of treatment—making a diagnosis before prescribing. After qualification doctors were submitted to the "anti-education" of advertisements, which often suggested that this or that drug was effective treatment for hypertension, anxiety, or even tiredness. It was necessary for doctors to be made proof against this.

Difficulties in Assessing Ill Effects

Making the final contribution to the symposium, Dr. M. J. LINNETT (London) described the uncertainties of drug administration, the unreliability of patients' evidence, and the resultant difficulty in assessing side-effects. There was often a contrast between theory and practice—books listed adverse reactions of drugs, but clinicians found the same substances effective and relatively free of ill effects. It was inevitable that new drugs carried some risk, but this could be limited if adequate information was readily available to the prescriber. Dr. Linnett listed suitable sources of information, among them the *B.N.F.*, journals, consultant advice, and drug-house literature, the latter being often surprisingly objective but needing a critical eye for evaluation of the evidence. The *Drug and Therapeutics Bulletin* (Consumers' Association), *Prescriber's Journal*, and the new *Proplist* published by the MacGregor Committee, were other valuable sources. In the future the early warnings sent out by the Dunlop Committee might usefully be expanded into a regular publication on drug side-effects and their frequency. In conclusion, Dr. Linnett made suggestions for safer prescribing. Doctors should use drugs with which they were familiar, find out if the patient had ever shown any drug sensitivity, inform him of the treatment being given and warn him of possible side-effects, and give notice of any that occurred on the Dunlop Committee's yellow cards.

Discussion

Subsequent discussion centred on the responsibility of consultants to ensure that all adverse reactions were reported, on the need for a wider distribution of yellow cards outside the N.H.S.—Professor WITTS said that this had already been arranged—and on means for doctors to find out rapidly whether a patient was already known to be sensitive to a particular drug. Professor MACGREGOR foresaw the time when doctors would be able to get information rapidly from computerized record-linkage systems. Referring to drug trials, Professor WITTS said that anything which purported to be done by human judgement or intuition could be done more efficiently by computer.

The President, Professor Hamid Ali M. Khan, Mr. Robert G. Cooke, Member of Parliament for West Bristol, and Mrs. Cooke at opening of the Scientific Exhibition.

Problems of Accident and Emergency Services

Mr. Norman Capener (Exeter) introduced the symposium on the problems of the accident and emergency services, which were now having to deal with a quarter of a million accidents each year. The total was rising, so it was vital that the services were efficiently organized and that proper rehabilitation was available for the injured.

Mr. H. Osmond-Clarke (London) said that accidents were now third on the list of causes of death in Britain. Last year 17,700 people had died in England and Wales as a result of accidents, and nearly half of these deaths had occurred on the roads. He outlined an organization of services which would include teaching hospitals and specially designed hospitals closely linked with general practitioners. Dr. R. M. McGregor (Hawick) presented his experience of accidents, and analysed the types of accident seen in 2,933 patients in his practice in the last 18 years. Most had been simple, and with beds available in a local hospital not more than 3% of patients had had to be transferred. The type and incidence of accidents varied with age and sex—for example, elderly female patients were more likely to have accidents than were elderly men, though the reverse of this situation was seen in young people.

Some patients were more prone to accidents than others. Important causes of accidents appeared to be overcrowding, lack of parental care in the young, and physical disability at all ages. It was important to investigate the causes of accidents in the home just as much as the cause of accidents on roads.

Rescue Equipment

Some of the appalling accidents on the roads which had occurred in his practice were described by Dr. K. C. Easton (Richmond, Yorks), and he underlined the need for proper provision of equipment to deal with rescue work. Road recovery vehicles with equipment that could free the trapped occupants of vehicles were essential. It was estimated that a quarter of patients involved in road accidents died on their way to hospital. Many lives could be saved if laryngoscopes, airways, and oxygen were available.

Dr. P. J. Roylance (Kingswood, Surrey) emphasized the need for maintenance of the airway by putting the patient on one side with the head down to avoid regurgitation of fluid into the lungs. Many of the patients dying soon after an accident did so from respiratory obstruction and aspiration pneumonia. Essentials such as the control of haemorrhage and the care of the unconscious patient needed to be stressed in the teaching of first-aid.

Mr. L. W. Plewes (Dunstable) showed how many specialist services were required in a modern accident service. To function efficiently these services must not be overburdened by trivia. General practitioners must be encouraged to form part of this service. Mr. H. H. Langston (Winchester) suggested that small inefficient local casualty departments should be closed, because there was not enough junior staff available. Effective consultant supervision was necessary to attract junior staff. Consultant supervision could reduce the burden on these centres by decreasing the number of patients needing repeated attendances or follow-up.

Accidents in Industry

Dr. R. A. Trevethick (Sheffield) said that little was known of the size of the accident problem in industry. Each year 700 people were killed as a result of industrial accidents, yet detailed figures were scarce. For some industries, such as trawler-fishing, no information was available. The figures derived from hospital statistics were misleading. In his own experience lacerations and burns formed the majority of industrial injuries. With adequate care 97% of injured workers were able to return to work within a week. A good standard of care was easy for large firms but very much more difficult for small firms, who would have to be encouraged to share services. He was disturbed at the inadequate planning for services to deal with industrial catastrophes in some areas.

Head Injuries

Mr. Walpole S. Lewin (Cambridge) discussed the problem of head injury. A quarter of a million head injuries occurred each year, of which over 10,000 required admission to hospital. Proper management included a careful assessment of the patient's level of consciousness, the condition of the pupils, the presence or absence of paralysis, and the state of the reflexes. Failure to show steady recovery in these signs must alert practitioners to possible complications. In addition to what had been said about the maintenance of the airway he would add that patients should not be warmed, they should not be given fluids, and should not have drugs—particularly analgesics. Even with the best management some 400 patients each year were unconscious for a month or longer, and this imposed a heavy burden on the medical and nursing staff. Rehabilitation units should not be asked too soon to take patients who had serious head injuries, because some would not benefit. To be suitable, patients need to be physically fit and to have regained their memory. Rehabilitation when used correctly could get some 80% of these patients back to their normal work.

Diabetes—the Present Situation

Current knowledge of diabetes was discussed in the modern trends series, with Dr. C. T. Andrews (Royal Cornwall Hospital) in the chair.

Professor J. Vallance-Owen (Belfast) described his work on plasma synalbumin insulin antagonists using the isolated rat diaphragm as a biological system. Initially he had found such antagonists to be present in plasma from uncontrolled insulin-dependent diabetics but not in that from obese or controlled insulin-dependent diabetics. However, on dilution of the albumin fraction antagonists had become detectable both in obese diabetics and pre-symptomatic (chemical) diabetics but not in normal people or patients with pancreatic diabetes.

Genetic studies had shown the synalbumin antagonist to be inherited as an autosomal dominant. Professor Vallance-Owen believed that patients who became diabetic were in hyperdynamic equilibrium with regard to insulin and synalbumin antagonists from birth, and he reported some studies on cord blood which supported this. He had also found evidence to suggest that ischaemic heart disease was in some cases genetically related to the presence of synalbumin antagonists.

Genetic Factors

Dr. D. L. Crombie (Birmingham) outlined a dynamic model of diabetes derived from studies carried out by a working party of the Royal College of General Practitioners. He thought that hyperglycaemic factors pressed insulin production beyond its limit and led to destruction of islet cells. In established diabetes an episode of hyperglycaemic stress frequently led to additional insulin requirements afterwards. Dr. Crombie regarded genetic factors as important only in patients who developed diabetes under the age of 30. In this group siblings were found already to have diabetes at the time of onset 26 times as often as in normal people, whereas the ratio was only 6 in the age group 30–49, and 1.5 over 70 years. Finally Dr. Crombie drew attention to the infinite variety and reversibility of the biochemical components of the disease, in contrast with the pathological complications such as retinopathy, nephropathy, and often neuropathy, which were progressive and irreversible. He put forward as a speculation the possibility that such complications were all secondary to the vascular effects of autonomic neuropathy.

Management

Dr. J. D. N. Nabarro (Middlesex Hospital, London) summarized the management of diabetes, emphasizing that in the absence of cure doctors must aim to relieve symptoms, maintain as normal a life as possible for the patient, and prevent complications, even though it was not known why these developed. Management was of paramount importance—physiological levels of blood sugar could be maintained by diet alone in 50% of the 2,000 patients he looked after. Where this was unsuccessful a further 15% could be controlled by diet plus tablets, and 35% needed insulin.

Dr. Nabarro then discussed oral hypoglycaemic drugs. The sulphonylureas stimulated the pancreas to produce more insulin. Tolbutamide was gentle and short-acting; chlorpropamide was the most powerful and could produce prolonged hypoglycaemia; glymidine, acetohexamide, and tolazamide were intermediate in potency and of little extra practical value. These drugs were remarkably free from side-effects, but dietary control was important, as patients often gained weight. Additional stress could render the drugs ineffective, and resistance could develop. However, a few months' control on insulin often made it possible to use drugs again. The diguanides (phenformin and metformin) apparently interfered with glucose utilization, so more glucose was used and the blood sugar fell. However, they had undesirable side-effects, and the theoretical loss of weight was seen in only 25% of cases. Nevertheless, combined therapy with chlorpropamide and phenformin had proved useful.

Insulins

Dr. Nabarro next gave an account of insulins. Antibody production was less with pork insulin than beef insulin. The proportions of these varied in different preparations. Dr. Nabarro said he had not been impressed with newer neutral-buffered or delayed-action insulins. Finally he referred to work suggesting that the mitotic rate in the pancreatic islets was increased by the administration of sulphonylureas. As a practical application of this work patients with pre-symptomatic diabetes had been treated with sulphonylureas. Their glucose-tolerance curves had been found to have become normal when repeated after a year. Further evidence supporting these findings might make the search for latent diabetics of great prophylactic value, Dr. Nabarro concluded.

Diagnostic Pitfalls in General Practice—the Abdomen

Opening a plenary session on diagnostic pitfalls in general practice, with special reference to the abdomen, the chairman, Sir JOHN BRUCE (Edinburgh), said that reputations could be made or marred by the diagnosis and treatment of abdominal disease. The first speaker, Dr. RONALD GIBSON (Winchester), pointed out the pitfalls that beset the general practitioner faced with a patient with abdominal symptoms. The first was to pay more regard to the textbook than to clinical acumen. The major pitfall, from which others stemmed, was failure to do a complete examination and to concentrate solely on the abdomen, assuming that the cause of the symptoms would inevitably be found there. This, said Dr. Gibson, was not only fallacious but dangerous. A history of the illness, a full physical examination, and the use of ancillary diagnostic services were essential for correct diagnosis. A second pitfall following an incomplete examination was that the patient might be sent to the wrong type of consultant for a second opinion. This was not a minor pitfall, as the patient might be operated on when he really had a condition —such as a basal pneumonia—that needed medical treatment. Dr. Gibson listed a number of conditions that might present with abdominal symptoms, including tabes, porphyria, lead poisoning, hypercalcaemia, sickle-cell anaemia, myocardial infarction, torsion of the testicle, and glandular fever.

Surgical Pitfalls

Speaking as a surgeon, Mr. R. V. COOKE (Bristol) stressed the paramount importance of a good history in making a diagnosis. A provisional diagnosis could often be made from a good history and one characteristic sign. If the patient had violent abdominal pain the doctor should consider vascular accidents, such as a leaking abdominal aneurysm or mesenteric thrombosis and embolism, or perhaps acute pancreatitis. Acute pain arising from the gall bladder was always very severe and frequently prevented adequate examination. Pain that developed after food was not always due to disease of the stomach or duodenum; it could result from a colonic lesion.

There were 3,000 deaths annually in this country from acute small-bowel obstruction, said Mr. Cooke. He attributed this to the fact that frequently there were no important physical signs and not much pain, and so there was delayed diagnosis and treatment. Diarrhoea was a symptom that should never be ignored—it might be the first evidence of carcinoma of the colon. Each year 500 patients died in England and Wales as a result of acute appendicitis. Mr. Cooke considered that this mortality could be reduced by earlier diagnosis and earlier operation. Signs and symptoms of a ruptured spleen were often minimal, particularly in children, who often recovered from the initial pallor and shock quite quickly. Faced with a difficult abdominal emergency the general practitioner should call in a consultant for a domiciliary visit without delay.

In the Wrong Bed

Dr. J. M. NAISH (Bristol) spoke of his experiences as a hospital physician. Frequently the patient referred by the general practitioner found himself in the wrong bed. Suffering from a medical abdominal emergency, he might be sent into a surgical ward. In his experience 10% of so-called acute surgical conditions eventually turned out to be medical emergencies. Fortunately the modern surgeon was also medically orientated and was quick to distinguish the two. Dr. Naish listed a number of medical conditions that had been admitted first to the surgical wards of his hospital. Among the biochemical disorders that had been diagnosed initially as surgical conditions because of symptoms referrable to the abdomen were ketosis, uraemia, hyponatraemia, hypercalcaemia (occurring in hyperparathyroidism, thyrotoxicosis, sarcoidosis, and vitamin-D poisoning), porphyria, and multiple myeloma. Heart failure with liver congestion, coronary thrombosis, pneumonia, pleural effusion, and pulmonary infarction were medical conditions that might have abdominal symptoms and be referred to the surgeon. So might Bornholm disease, irritation of the spinal roots (for example, from osteoarthritis, collapsed vertebrae, and osteomyelitis), and diseases of the blood vessels such as purpura, sickle-cell crises, mesenteric angina, and polyarteritis nodosa.

Infancy and Childhood

The assessment of abdominal pain in infancy and childhood was discussed by Professor N. R. BUTLER (Bristol). He explained that the history was usually obtained secondhand through the mother and that adequate examination, particularly in the infant, was frequently difficult. Even obtaining a urine specimen might entail an "all-night sitting." The younger the child, the greater was the danger of perforation of an acute appendix or of gangrene from an intussusception—to which the key in diagnosis was palpation of the abdomen when the baby was feeding and relaxed. Professor Butler said that he had seen more cases of acute abdomen in two years of general practice than in 15 years as a paediatrician. The general practitioner had the advantage of knowing the family, which was a help in deciding if the pain was acute and if so how acute.

Recurrent abdominal pain was present in about 15% of Bristol children aged 7. Professor Butler said that as a result of a survey of Bristol children complaining of abdominal pain Dr. J. Apley had found

The President Elect, Mr. R. V. Cooke, opening the Scientific Exhibition.

organic causes in only 10%. It was the psyche that grumbled rather than the abdominal organs. More abdominal pain was engendered in children today by unsympathetic teachers and insecure parents than ever before. Many such children went on to develop the "periodic syndrome" and later on migraine.

Help from Radiology

Dr. T. LODGE (Sheffield) indicated how the radiologist might help the general practitioner to avoid diagnostic abdominal pitfalls. Radiology, however, did not give the final answer to diagnosis. The findings should be regarded by the general practitioner as no more than a facet of the problem, and considered in the light of his clinical examination and history. Indeed they could be definitely misleading unless they fitted into the clinical picture. On the other hand, "double pathology" might be revealed by the radiologist with the less serious condition providing the presenting symptoms. Dr. Lodge said that he observed many cases of hiatus hernia as incidental findings. In infancy it was of serious significance, but in adults it should be ignored if symptomless.

Recent surveys had shown a high incidence of organic disease in patients with "globus hystericus." Mental disturbances were not unusual in a number of gastrointestinal complaints. The site of abdominal pain in children was frequently misleading. The diagnosis of intussusception could be confirmed by straight radiography of the abdomen and by a barium enema, which under screen control could reduce an intussusception or make its final surgical reduction easier.

In the discussion that followed Dr. NAISH considered that the general practitioner should have access to diagnostic radiological services, but Mr. COOKE disagreed. Dr. NAISH said that it was harmful if not dangerous to do a laparotomy if the patient had a medical emergency such as a coronary thrombosis, pulmonary infarction, diabetic coma, acute porphyria, or hepatitis. Joining in the discussion, Mr. A. DICKSON WRIGHT (London) considered that every acute abdomen with severe pain was a surgical condition, but care should be taken not to do emergency operations on cases of renal colic or pancreatitis.

Vocational Training for General Practice

Wednesday, 12 July

With LORD COHEN OF BIRKENHEAD (Liverpool) in the chair, members of the panel made brief opening statements on "Vocational Training in General Practice." Lord Cohen said that although vocational training had been rejected when incorporated into B.M.A. reports of 20 years ago, it was now the theme of all curricular discussions. Dr. P. S. BYRNE (Milnthorpe) insisted that vocational training must be part of a flexible system, that there must be teachers, and that the new well-trained generalists must escape from the Cameron–Finlay myth. Professor R. SCOTT (Edinburgh) said a vocational training system had to be experimental, and that individual medical schools should get out into the community and use it as their laboratory. More had to be invested in testing methods of training. Dr. R. P. W. SHACKLETON (Southampton) suggested that the regions were the places for vocational training for both the general practitioner and the specialist. The task of postgraduate advisers was to introduce a new pattern of rotational hospital appointments suitable for both. Dr. G. SWIFT (Winchester) thought of the organization of vocational training as a problem for regional hospital boards and local medical committees to deal with together. He emphasized the need for trainees to have opportunities to see each other as well as other practices, and to observe the local authorities at work, and to maintain contact with the university.

Place for Obstetrics

After vigorous discussion on whether general practitioners would do obstetrics in the future and whether this should be a "must" for vocational training, LORD COHEN reminded the meeting that normal obstetrics and the recognition of emergencies was taught to the undergraduate, and this knowledge was available to be built on in the postgraduate period if necessary.

Dr. A. M. GOLDTHORPE (Saskatchewan) asked for what basic type of practice the vocational training was intended. Professor SCOTT thought that students were better trained than they were given credit for—perhaps too well for general practice in that they expected not to be in isolation, to have facilities for investigation and treatment, and to be in direct relationship with the hospital and community centres. Dr. GOLDTHORPE replied that it was not attractive to young men to be trained in hospitals and then excluded from them. In Canada the general practitioner was observed for a year and then allotted duties in the hospital in accordance with his abilities, so that 85% of total medical care was carried out by general practitioners.

Use of Examinations

Asked whether a qualifying examination was of any value at all, Dr. BYRNE said that in spite of 104 diplomas already in existence the Royal College of General Practitioners intended to introduce another. He hoped that it would have a high pass rate and be used not only to see that some teaching rubbed off on the students but as a test of that teaching. Dr. SWIFT said that his education had not taught him how to educate himself, and the qualifying examination should test this. Dr. SHACKLETON pointed out that Yale had no qualifying examination and that each student had his own tutor whose progress reports were used to assess him. The General Medical Council, under Lord Cohen, also thought continuing assessment as important as the examinations.

The role of local health departments in general-practitioner training was considered. Professor SCOTT thought they should be responsible for health centres and should investigate the questions of automation and the use and value of records. Dr. BYRNE wanted to compare health centre practice with good general practice. Ideally the health centre would be associated with a medical school. Dr. SWIFT suggested the one-week visit of trainees to the local health authority, as in Hampshire, was of great help in informing them of facilities and services that were available, but medical officers of health had to be forward-looking too.

Dr. BYRNE thought that general practitioners and practices for vocational training should be selected from applicants by an appointments committee as for any other teaching post. Professor SCOTT tried to select doctors who could stand criticism by both students and patients in the teaching situation. Dr. SWIFT had concluded from trainee courses he had run that many practitioners were natural teachers, while Dr. SHACKLETON emphasized the value of the postgraduate medical centres as meeting-places of the whole profession in recognizing suitable teachers informally.

LORD COHEN concluded that medical education was always striving for an ideal goal which would never be reached. So far the General Medical Council had been able only to observe the new experiments—if it were ever able to initiate them vocational training in general practice would be the first field it would tackle.

Bereavement

Opening the panel discussion on bereavement, the chairman, Professor D. RUSSELL DAVIS (Bristol), said that it was the duty of family doctors to care for the rest of the family as well as the dying patient. Both speakers at the discussion had made systematic inquiries on bereavement—a field previously explored only by writers, poets, and dramatists.

The first speaker, Dr. C. MURRAY PARKES (Tavistock Institute of Human Relations), described studies of bereaved people in London, and said that only one-third of London widows had any contact with a clergyman apart from the funeral service, whereas three-quarters consulted a general practitioner during the six months following bereavement. The number of consultations showed a sharp increase following bereavement, the reasons for seeking advice being different at different ages. Young widows—those under 65—suffered mainly from psychological difficulties, and their consumption of sedatives increased sevenfold during the 18 months immediately after their husbands' deaths. In the older age group, on the other hand, physical symptoms accounted for most of the increase in consultations and there was little change in sedative consumption. The mortality rate of widowers over 65 increased sharply in the six months after bereavement, and studies had shown a 50% increase in deaths from coronary disease compared with the expected rate for married men of the same age. The old idea of dying of a broken heart seemed not to be far wrong.

Dr. Murray Parkes went on to describe the phases characteristic of grief and mourning, during which the widow was initially shocked or numbed, and then suffered from pangs of intense pining. In the final stage there was revival and a gradual return to normal life. There were wide variations in this pattern, and a typical form of grief had been seen in 21 bereaved patients admitted for psychiatric treatment. The reactions in these patients had been precipitated by such factors as overdependence on the dead person, hostility, isolation, and the actual mode of death. Bereaved people could be helped by support before and after the death of a relative and by lending a sympathetic ear. The doctor's task was to treat the whole patient, to allow a reasonable period of grief and mourning, and then to make it clear that there was a time to stop. It was not yet known whether antidepressives should be used or whether they merely postponed the period of grief. Cruse Clubs could help widows and had published two useful booklets.[1]

Ritual Mourning

Mr. GEOFFREY GORER (Haywards Heath, Sussex), author of *Death, Grief and Mourning in Contemporary Britain*, described his own inquiries as a social anthropologist into ritual and deritualized mourning. He pointed out that bereaved people no longer knew how they should behave unless they belonged to a religious group such as Orthodox Jews, members of the Church of Scotland, or Roman Catholics of Irish descent, who still practised ritual mourning. Following a period of grief and mourning bereaved people in these groups adapted well to their loss, and all the evidence—contrary to the speaker's own expectations and personal feelings—suggested that the process of burial of the corpse and ritual mourning was helpful, while cremation was more commonly associated with serious disturbances among the bereaved.

Mr. Gorer went on to say that mourning was deritualized for most people in England today; social disapproval stigmatized the grief-ridden as undesirable, so that they were socially ostracized until they bottled up their feelings, and even outward signs of mourning were not favoured socially. In interviewing bereaved people he had found that they welcomed the opportunity to talk about feelings which had previously been repressed. "Satisfactory normal mourning" consisted of three stages. The first was a short period of shock, which lasted normally up to the burial. Next came a period of intense grief, its length determined by the individual's feelings, since there was now no commonly accepted religious prescription for this. Finally, there was a gradual return to normal life. Among bereaved people who failed to adapt satisfactorily some never entered the second stage because they denied their grief. This was particularly common among widows of professional men. Others never left the second stage, and these included working-class widows over 50, who said with some pride that they would never get over their loss.

Concluding, Mr. Gorer regretted that many doctors appeared to subscribe to the view that grief was morbid. In his opinion it was better to allow the manifestations of grief to work themselves out.

The discussion centred on whether dying patients should be told the prognosis—a proposition supported by Mr. Gorer but contested by several speakers from the floor.

Place of Surgery in Acquired Cardiac Disease

A panel discussion on the place of surgery in acquired cardiac disease was held under the chairmanship of Sir THOMAS HOLMES SELLORS (London). The indications for surgery in mitral stenosis were described by Professor J. F. GOODWIN (London). Valvotomy was required when increasing dyspnoea, haemoptysis, or bronchitis was associated with signs of tight mitral stenosis. Operation should be delayed in the absence of symptoms because of the possibility of restenosis, said Professor Goodwin, but if auricular fibrillation supervened the treatment required was anticoagulation, followed by valvotomy. Pregnant patients with acute symptoms due to mitral stenosis did well following valvotomy. If congestive cardiac failure developed early in the course of the disease this should arouse a suspicion of complications. Doctors should look for early clinical, radiographic, and electrocardiographic evidence of pulmonary hypertension, as valvotomy could reverse this complication if done early enough.

Factors which influenced the success of mitral valvotomy adversely included a rigid mitral valve, valve calcification, an enlarged heart, increasing age of the patient, the possibility of active carditis, and ischaemic heart disease. Patients aged over 50 years did well in the absence of these factors. Restenosis after valvotomy was a problem and seemed to occur less when a valve dilator was used. Professor Goodwin advocated long-term prophylactic sulphonamide therapy after valvotomy.

Professor Goodwin then discussed mitral incompetence. There was much less experience with valve replacement than with valvotomy, and it was still accompanied by a high risk. Patients with mitral incompetence tended to run a more rapid downhill course after the arrest of symptoms but probably had a better prognosis than had been previously thought. They were more prone to such complications as subacute bacterial endocarditis. Mitral regurgitation secondary to papillary necrosis after myocardial infarction was also amenable to surgery.

Aortic Valve Disease

Dr. D. W. BARRITT (Bristol) dealt with aortic valve replacement. The major symptoms of aortic valve disease were dyspnoea on exertion, paroxysmal nocturnal dyspnoea, orthopnoea, angina pectoris, and sudden loss of consciousness. Dr. Barritt reported on a series on 51 patients treated with aortic valve replacement using a Starr–Edwards prosthesis. Seventeen had died in hospital, four had died later as a result of intractable left ventricular failure, cerebral embolus, or myocardial infarction, and 30 patients were still alive. Whenever possible these patients were given anticoagulant therapy.

Mr. R. H. R. BELSEY (Bristol) agreed with Professor Goodwin on the importance of deciding the right time for valvotomy, especially as it had been suggested that the incidence of restenosis was as high as 10%. It was very important that unnecessary operations on unsuitable patients were avoided on the grounds of economics alone.

Mr. D. N. ROSS (London), discussing the selection of patients, suggested that more attention should be paid to the state of the myocardium and that methods should be developed to enable this to be done.

Discussion

The meeting was then thrown open to questions. Dr. D. A. GRIFFITHS (Bristol) asked to what extent multiple valve replacements were done. Mr. Ross said that the other valves were always explored at operation and all mechanical disabilities were dealt with. Mr. BELSEY said that valvuloplasty rather than replacement might sometimes be possible. Professor GOODWIN advocated the use of aortic valve homografts in multiple operations because of the rising risk of embolic complications after multiple prosthetic replacement. Mr. ROSS thought that homografts should be used for aortic valve replacement except when an aortic aneurysm was present, when a patient was very ill and operating time needed to be short, and in multiple valve replacement, where an aortic prosthesis did not add significantly to the risk from the mitral valve prosthesis.

Headache

A panel discussion on headache was chaired by Dr. A. M. G. CAMPBELL (Bristol). The opening speaker, Dr. MACDONALD CRITCHLEY (London), said that headache was probably the commonest symptom in medicine, but fortunately it was rarely due to neurological or cranial disorder. It could be the presenting symptom of many toxic, metabolic, infective, and psychiatric conditions, as well as the sequel of a hangover. It could be trivial and temporary or herald a cerebral catastrophe.

Headaches were caused by alterations in the calibre of the cerebral vessels. An intensive search was being made for metabolic substances capable of causing headache and also for their pharmacological antagonists. Some drugs with an antiserotonin action could relieve headache. Some people never experienced headache, and it might be rewarding to study them.

Headache provided a valuable exercise in differential diagnosis, said Dr. Critchley in conclusion. Careful questioning about frequency, nature, severity, and influencing factors was necessary to discover the cause.

Incidence

Dr. S. J. CARNE (London) described the incidence of headache as a prescribing symptom in 6,000 patients seen in a London general practice. The overall incidence had been 1 in 15 patients (6.6%). Headache was commonest between the ages of 5 and 44. Women suffered more than men and immigrant West Indians more than the native British population. Dr. Carne said that the vast majority of patients associated headaches with some visual defect, with a brain tumour, or with hypertension—though many cerebral tumours did not present with headache and hypertension was seldom a cause. True sinusitis was rarely responsible, though nasal obstruction due to allergy or catarrh might produce headache. Worry and anxiety were potent causes. It was essential in all cases for the practitioner to make a complete examination and to reassure the patient if he found no obvious disease. An *x*-ray of the skull usually satisfied the chronic worrier that his headache had no cerebral cause. In Dr. Carne's experience the commonest causes of acute headache were infections, including influenza and tonsillitis, and in the summer excessive exposure to sun. Chronic headache was frequently associated with migraine, depression, and upper respiratory catarrh.

Psychogenic Headache

Dr. DAVID STAFFORD-CLARK (London) said that a headache was often the presenting symptom of depression and anxiety. The nature of the pain was different in the two conditions, that associated with anxiety being splitting or tearing in nature, while that accompanying depression was dull and like a tight band round the head. Mental tension, worry, and distress could be projected into the symptom of pain. Headache thought to be due to the post-concussion syndrome was experienced by some patients who in fact had never been concussed, but who were reacting to stress.

Ophthalmic Causes of Headache

Ophthalmic causes of headache were rare, said Mr. R. A. BURN (London). Of 1,018 cases referred to him for an ophthalmic opinion only 13% had had pain in the head or eyes, and 39% of these had been cases of anxiety without eye disease. Ocular conditions that cause headache or pain behind the eyes were mainly functional abnormalities of the ocular muscles, followed in frequency by corneal lesions, uveitis, and acute glaucoma. Headache might be due to the strain of accommodation in patients with hypermetropia and presbyopia, but not in those with myopia. In headache of ocular origin the pain was felt in and around the eye. Small children, young people facing the stresses of life for the first time, and older persons with diminished visual activity sometimes suffered from what might be termed "ocular anxiety." They experienced pain of ocular type, but no ophthalmic condition could be found to account for it.

In reply to a question Dr. CRITCHLEY said that hypertension aggravated migraine. Some patients with the condition suffered from cerebral anteriolar sclerosis later in life. He considered that cranial arteritis as a cause of headache was rare below the age of 65. Dr. Carne thought that true allergy was rarely a cause of headache.

Cytotoxic Drugs in the Treatment of Malignant Disease

Cytotoxic drugs in the treatment of malignant disease was the subject of a further "Modern Trends" meeting, with Professor A. G. RIDDELL (Bristol) in the chair.

Professor Riddell described the overall results of systemic chemotherapy as "pretty grim." Many patients responded badly, but very occasionally the outcome was more successful. Choriocarcinoma treated with methotrexate and nephoblastoma with actinomycin D were exceptions to the poor results. It was probably not a good idea to cover operations for cancer with prophylactic cytotoxic agents, because these drugs impaired the immunological mechanisms at a vital time. Professor Riddell reported the use of an immunological approach in conjunction with cytotoxic drugs. Five patients with advanced malignancy had been given 20 mg. of melphalan 10 hours before the intravenous injection of 4×24^9 suspended human spleen cells. These patients had shown a temporary response to treatment. In another patient the spleen had been removed, an extract of the tumour had been injected into a pig, and a suspension of cells from the pig's lymph glands returned to the patient. There had been a dramatic reduction in the site of the tumour. These were tentative steps towards a rational programme.

Choice of Drugs

Dr. J. INNES (Edinburgh) said that the beneficial effects of cytotoxic agents were almost entirely confined to mesodermal neoplasms. The alkylating agents were radiomimetic, and some were fairly specific—for example, busulphan in chronic myeloid leukaemia. The antimetabolites such as methotrexate and 6-mercaptopurine had been introduced as a result of study of the fundamental biochemistry of cells, and had an important place in childhood leukaemia. In a miscellaneous group were urethane, antibiotics, and the periwinkle alkaloids. Generalized therapy was indicated for generalized disease, but radiotherapy was to be preferred for localized lesions. No striking new drugs apart from vincristine and vinblastine had appeared since 1954. Such improvement in results as had been achieved was the result of many clinical trials and a joint therapeutic approach by physicians, surgeons, and radiotherapists.

Perfusion

Mr. C. I. COOLING (London) described the techniques of isolated limb perfusion and regional infusion. In the former the limb was connected to a heart–lung machine and the cytotoxic drug was added to the perfusion fluid in a dose limited only by the tolerance of skin, muscle, and nerve. A tourniquet prevented the drug from reaching the general circulation. Perhaps 10% of patients had good results, though pain was relieved more often. With regional infusion a high dose of drug (usually methotrexate) was given intra-arterially over a period of 7 to 14 days. A dye was used to show the area perfused, and an antidote given intramuscularly helped to lower the systemic level. Good results had been obtained in tumours of the head and neck and of limbs. Dr. Cooling hoped that further research might produce drugs tailor-made for particular tumours, which would improve the value of these useful palliative techniques.

Natural History of Enuresis

Introducing the speakers in the session on the natural history of enuresis, the Chairman, Dr. JOHN APLEY (Bristol), said that, though doctors knew what they meant by the term enuresis, it defied precise definition. With certain qualifications it could be defined as incontinence of urine without demonstrable cause at an age when control had normally been achieved. Enuresis was subdivided into diurnal and nocturnal, primary and secondary; the last having its onset after a period of full control.

Dr. J. W. B. DOUGLAS (M.R.C. Unit for the Study of Environmental Factors in Mental and Physical Illness) described the results of a prospective study of 5,000

The chairman and speakers at the Modern Trends Lecture on Cytotoxic Drugs in the Treatment of Malignant Disease. Left to right, Professor A. G. Riddell (chairman), Mr. C. I. Cooling, and Dr. James Innes.

children from birth to 15 years for investigation of the influence of factors during the first four years of life on the later development of enuresis. The overall incidence of enuresis at the age of 4½ was 13.6% in boys, and 10.6% in girls. Events such as infectious diseases, operations, burns or fractures, and separation from home and family all increased the prevalence of enuresis, so that the incidence in the group exposed to stress was 19%, while it was 7.6% among the remaining children. Stress in early childhood was clearly associated with enuresis later, even on the restricted recording of stressful events that had been possible in the survey.

Investigations

Speaking as a urologist, Mr. Ashton Miller (Bristol) discussed the examination and investigation of enuretic children and said that positive findings were rare. It was, however, important to spot children with underlying abnormalities and to exclude infection, which sometimes caused enuresis in girls. Cystoscopy had been done on a series of enuretic children, and Mr. Ashton Miller had found two types of bladder—each related to a different clinical picture. In children who were wet only at night the bladder had been normal, but in those with urgency and increased frequency of micturition by day as well the bladder had been smaller with a thicker, more muscular wall, and bladder neck hypertrophy. From these findings it had been possible to derive a plan for investigation of enuretic children. If the child was normal by day detailed investigation was unnecessary; if in the second group, and improving by day, it was reasonable to defer investigation as further improvement—first by day and later by night—was likely; but those who failed to improve by day (or even deteriorated) required full investigation.

Psychiatric Factors

Giving a psychiatrist's view of enuresis, Dr. Robert F. Barbour (Bristol) said that, while other body habits were allowed to develop naturally, toilet training was a "must," parental attitudes being typified by Wesley's saying, "Cleanliness is next to godliness." The first task of treatment was to relieve parental pressure on the child. Between the ages of 1 and 3 it was best to wait for spontaneous improvement (giving boys longer than girls), but between 3 and 5 years organic disease had to be excluded. Parents needed reassurance, and simple physiological methods of treatment were appropriate. These included restriction of fluids and waking the child an hour after going to sleep and an hour before the normal time of waking. Drug treatment and alarms could be used from the ages of 5 and 7 respectively.

Closing the meeting, Dr. Apley expressed the hope that Dr. Douglas's study on the effects of stress in early childhood might lead in the future to methods of preventing enuresis.

On Withholding Antibiotics

Thursday, 13 July

Professor C. Bruce Perry (Bristol) took the chair for the discussion on "Withholding Antibiotics."

Professor O. L. Wade (Belfast) had no doubt that the practice of medicine was becoming more difficult, particularly in the use of antibiotics. The organism had to be identified and therapy tailored to it with the help of a bacteriologist. It was becoming difficult to convince students that patients ever recovered from a fever without an antibiotic. Comparing patients with exacerbations of chronic bronchitis to whom antibiotics were given with those to whom they were not, he had found that the duration of the acute phase was not decreased. The mortality from chronic bronchitis had not improved in spite of the introduction of successive antibiotics. He now used them only when the sputum was really purulent, when there was a high fever, or when there was evidence of pulmonary consolidation.

General Practitioner's View

Dr. M. B. Lennard (Bristol) gave the view of the general practitioner who thought that antibiotics should not be withheld. Memories of acute osteomyelitis, mastoiditis, and fulminating pneumonia loomed larger to him than the risks of allergy or resistance. The age of the patient, his medical history (including response to antibiotics previously taken), local knowledge, and the known natural history of the infection were considered by the practitioner. Ultimately, the wisdom of the decision whether to use antibiotics was shown by the therapeutic response.

Antibiotics in Prophylaxis

Professor W. A. Gillespie (Bristol) discussed the use of prophylactic antibiotics. Many studies had shown these to be ineffective in surgical practice because the drugs were too selective, the tissues could be protected from one organism but invaded by another, and drug resistance could develop. However, in certain circumstances, such as dental operations in patients liable to subacute bacterial endocarditis, or patients at risk from clostridial infection after limb amputation, antibiotic cover was amply justified. Sometimes aseptic and antiseptic techniques had proved more effective than antibiotics—for example, in a nursery where babies were treated with hexachlorophene skin infections had been less frequent than when they were given erythromycin. The incidence of breast abscesses in the mother had also dropped on this regimen.

Mr. A. Dickson Wright (London) discussed the age-old propensity for man to dose himself with medicine. Nowadays the medicines tended to have pharmacological effects, and 30% of diseases were said to be iatrogenic.

In the ensuing discussion Professor Wade said he regarded mucolytic agents as unhelpful in chronic bronchitis. The general-practitioner view was that short courses of antibiotics did not mask serious infections, but Mr. J. Angell James (Bristol) thought that mastoiditis could be masked by inadequate treatment of otitis media until meningitis developed. Professor Gillespie reminded the audience that organisms were not killed all that quickly by antibiotics, and that in the Bristol area 60% of staphylococci outside the hospitals were resistant to penicillin.

Diarrhoea

A symposium on diarrhoea was chaired by Mr. W. M. Capper (Bristol). The clinical approach was discussed by Dr. A. E. A. Read (Bristol), who defined diarrhoea as too rapid an evacuation of too fluid stools; the actual number of stools passed daily was of no consequence. The important factors were the colour of the stools and the presence of blood or mucus. The causes of diarrhoea were numerous and included diseases of the large and small bowel as well as generalized conditions such as thyrotoxicosis. Antibiotics, malabsorption syndromes, alcohol, and infections were other possible causes. A careful personal, family, and social history was essential and a complete physical examination should be done in all cases. Rectal examination, tests for occult blood, urinalysis, sigmoidoscopy, and a barium meal should be included in every examination, with bacteriological investigation in times of epidemics. In hospital, tests for malabsorption and thyroid function, and arteriography to detect possible thrombosis and arteriosclerosis of vessels of the large intestine, might be necessary. Dr. Read mentioned the association between certain skin diseases and diarrhoea, and the possibility that virus diseases, small bowel stasis, and genetic disaccharidase deficiencies might be factors in causation.

Use of Radiology

Dr. J. W. Laws (London) explained that radiological investigation was of particular value in aiding the diagnosis of localized lesions in the colon, as in diverticulitis, ulcerative colitis, Crohn's disease, neoplastic disease, and the presence of anatomical abnormalities. Normally a barium enema was done first, and then a barium follow-through if indicated. It was advisable to examine the small bowel radiologically with the patient erect as well as supine, as fluid levels could then be discerned. Other small bowel lesions that could be visualized were stagnant loops, diverticula, strictures, abnormal mucosal patterns, fistulae, and dilatations. Radiology of the small intestine was useful in the diagnosis of conditions in which the mucosal pattern was abnormal, such as coeliac disease, steatorrhoea, Whipple's disease, defective disaccharide absorption, and other malabsorption syndromes.

Pathology of Colonic Disease causing Diarrhoea

The term ulcerative colitis was a misnomer, said Dr. B. C. Morson (London), as it was not primarily a disease of the colon, but rather of the rectum. The colon was shortened not by fibrosis but by thickening of the muscle, and as a result of sustained spasm and hypermotility it could not retain its contents adequately. The mucosal surface was granular, haemorrhagic, and packed with congestive blood vessels—like a hyperaemic burn of the skin treated with a faecal poultice. Later the mucosa became secondarily infected and infiltrated with round cells. Dr. Morson suggested that ulcerative colitis might be a hypersensitivity reaction, possibly to histamine.

Next he defined Crohn's disease as a granulomatous condition affecting any part of the gut from the stomach to the anus. The lesions, unlike those of ulcerative colitis, were discontinuous and were more frequent in the terminal ileum and anal region. They were transmural rather than submucosal and sarcoid foci were present in three-quarters of the cases. Bleeding was less frequent than in ulcerative colitis, which could be distinguished histologically in biopsy specimens. Turning to other causes of diarrhoea, Dr. Morson said that stricture of the splenic flexure occurred in elderly patients as a result of ischaemia of the local vessels. This caused abdominal pain, diarrhoea, and blood in the stools. Diverticulitis was not primarily inflammatory, but was caused mainly by segmental thickening of the circular muscle coat of the colon. Blocking of the diverticula caused stasis and secondary inflammation.

Malignancy in the Lower Bowel

Sir CLIFFORD NAUNTON MORGAN (London) said that the diagnosis of carcinoma of the lower bowel was frequently delayed for as long as six to twelve months because the symptoms were vague and often overlooked. Any change in bowel habit, the passage of blood or mucus per rectum, or the presence of abdominal tenderness in patients after the age of 50 should arouse suspicion. If seen early enough 95% of patients could be saved. Discussing the indications for operation in diverticulitis, Sir Clifford said that surgery should be considered if medical treatment failed, if bleeding was present, or if a mass could be felt. Diverticulitis could be premalignant. Patients suffering from ulcerative colitis for more than five years should be watched for the possible development of carcinoma. Papillomata of the rectum or colon should be removed, as they were also premalignant.

In the discussion that followed Dr. READ said that if unexplained diarrhoea was present for more than 10 days full clinical and laboratory investigations should be done. Sir CLIFFORD NAUNTON MORGAN considered that an exploratory operation should be done on all patients with unexplained rectal bleeding. He never used morphine or codeine for the relief of abdominal symptoms, as these drugs caused spasm of the smooth muscle of the bowel.

Cardiac Emergencies

A symposium on cardiac emergencies was held under the chairmanship of Dr. D. H. DAVIES (Bristol). Dr. D. G. FRENCH (Newcastle, Staffs) based his talk on a six-year experience in a practice of 6,000 patients. He told the meeting that he found an awareness of premonitory symptoms and electrocardiographic studies helped in the diagnosis of myocardial infarction. Among uncommon causes of heart failure he listed silent myocardial infarction, severe iron-deficiency anaemia, and atrial fibrillation secondary to occult thyrotoxicosis. Stokes–Adams attacks, paroxysmal tachycardia, and dissecting aneurysms were seen occasionally. More common was the occurrence of embolism and acute pulmonary oedema in patients with mitral stenosis; he emphasized the importance of the practitioner keeping in mind the patients with this condition, so that the emergencies might be anticipated.

Dr. D. G. JULIAN (Edinburgh) said that the acute myocardial infarction presented a complex of emergencies, of which ventricular fibrillation was the most important. It was best treated immediately with a difibrillator, but if this was impossible external cardiac massage and artificial respiration should be started. Ventricular fibrillation could be prevented by the prompt treatment of ventricular extrasystoles, and tachycardia with lignocaine and procaineamide. Asystole was a difficult form of cardiac arrest to treat, but intravenous isoprenaline might be helpful, or intracardiac pacemaking might be required. The management of shock in myocardial infarction remained a problem. The administration of oxygen and small doses of pressor amines was still the best treatment. At Edinburgh collection of patients with myocardial infarction in one unit with specially trained staff and specialist equipment had resulted in the saving of a fifth of the patients who might otherwise have died.

Anaesthetic Emergencies

In discussing complications that might occur during anaesthesia and the immediate postoperative period, Dr. G. W. BURTON (Bristol) emphasized the necessity for supplementing clinical observations with monitoring equipment. He considered that in operations where marked circulatory changes were likely it was essential to have facilities for electrocardiography and electroencephalography, for measuring arterial and central venous pressure, and for taking blood samples. The electroencephalogram was very helpful in deciding whether the circulation to the brain was adequate. The onset of slow waves in the E.E.G. and flattening of the waves was a sign of anoxia.

Other Emergencies

Dr. H. GORDON MATHER (Bristol) dealt with cardiac emergencies other than those particularly associated with ischaemic heart disease and anaesthesia. Acute pulmonary oedema might be due to hypertension, rheumatic heart disease, the sudden onset of atrial fibrillation, silent myocardial infarction, or overtransfusion. It was best treated by intravenous frusemide, digitalis, oxygen, and morphia. Hypertensive crises might occur in the course of long-standing hypertension from any cause; it might be seen in renal disease, pregnancy, phaeochromocytoma, or in adverse reactions to drugs such as monoamine-oxidase inhibitors. Such a crisis could present as acute pulmonary oedema, subarachnoid haemorrhage, acute cerebral oedema, and dissection of the aorta. It was often possible to control the crisis by the use of diuretics, digitalis, and sedatives. If it was necessary to give a hypotensive agent Dr. Mather said he still preferred pentolinium 2.5 mg. intramuscularly, followed by control with guanethidine.

Dr. Mather went on to say that adverse reactions to certain drugs could produce cardiac emergencies. Even well-established drugs such as digitalis could result in arrhythmias of every variety. Arrhythmias could complicate digitalis therapy when the patient had a low serum level of potassium, and adequate supplements must be given. Propranolol, a β-receptor blocker, might induce heart failure or hypertension, and could make bronchospasm worse.

WITHOUT PREJUDICE

As this is my last but one appearance on this page I should begin by apologizing to the many people who have written letters to me and have had no reply. My anonymity makes a correspondence difficult. I have stuck to the anonymity imposed on Pertinax when this column began in January 1963.

Writing under (or over) a pen-name is a respectable convention. When Oliver Edwards brought out in 1957 a collection of his weekly literary pieces from *The Times* under the title of *Talking of Books* neither he nor his publisher dropped the mask of anonymity he preferred to hold in front of his face. I am sure it gave him a feeling of freedom. "Now I can write what I please," he must have said to himself, "and not what in my persona propria I would be *expected* to write."

The first meaning of persona is "a mask, esp. that used by players, which covered the whole head, and was varied according to the different characters to be represented." The meaning was then transferred to the part or character one assumed in the world, from that to a human being performing any function, and later just to a human being. The wrapper round *Talking of Books* had this little message for the curious: "There have been many speculations as to the identity of Oliver Edwards. It is sufficient that he enjoys reading and writing and passing his enjoyment on."

And so do I, though I have nothing like the same range of reading to draw upon. But this is a professional journal, and Pertinax is a professional man with an itch to argue a case for and against it almost matters not what. Point and counterpoint; thesis and antithesis; against pomp, cant, and pretence; for decency and honesty of statement—these have been some of the guide-lines for this column, however much I may have failed to follow them.

I have been embarrassed on at least two occasions by speculations about my identity, but now I am leaving this particular stage I hope I may take my persona and mask into obscurity. But before I do this next week I shall try to answer one or two letters.

* * *

I quite expected criticism of my remarks on psychiatry in my piece of 17 June. But a psychiatrist with his D.P.M. said he was delighted with it. And what scribbler wouldn't be pleased to hear that? "It becomes increasingly obvious, to me at least," he writes, "that psychiatry is going further away from general medicine rather than closer. I am quite certain that much of the cleaving to general medicine by psychiatrists is an attempt to raise their consultant status to the status (real or imagined) of general physicians and surgeons, and all the pomp and ceremony that often goes with them." Well I am glad to have this bit of prejudice confirmed. "The longer I work in psychiatry, and particularly, of course, in a day hospital, the more I realize how much anthropology, sociology, philosophy, and all these bits and pieces which have to do with people living, are needed to do the job properly." He is sure "that medicine should continue to provide the bulk of psychiatrists, however, but that the training should be different." I am sure we shall get a burst of activity when psychiatry comes of age and has a latch-key to its own college.

I drew attention in the same article to the experiments in the U.S.A., and also in at least one centre in Britain, in which the medical profession were training the clergy in psychiatry. I suggested that the parish priest so trained would be a better general practitioner in mental health than the ordinary medical man. My reference was no more than a newspaper report. So I was more than pleased to get from the Revd. John Barton the programme of the Third Pastoral Clinical Training Course for Theological Students which ended last week. It was held under the auspices of the Leeds Regional Hospital Board and the Wakefield "B" Group Hospital Management Committee. Mr. Barton tells me in a letter that they have complete co-operation from regional board, hospital management committee, and the medical profession. "This year we have Anglican, Free Church, and Roman Catholic students in residence." I call that magnificent and heartening news.

Almost by the same post came two letters from New Zealand which one of these days I shall try to answer. A short time ago a leading figure of a sister profession asked me to let him have some hints and tips on a presidential address he had to give. Anyhow, I thought, I am at least leaving this page when people seem to be reading it.

* * *

Then two general practitioners have had a go. One from the far north of England believes that "there are two medico-political bees which appear to be nesting in your bonnet and which have little support in this part of the periphery. The first is your recurrent plea, on various grounds, that the patient should pay something at the time of service, the basic idea being that this somehow improves the quality of medical care. Frankly I do not believe that money will make any difference in the vast majority of doctors." How representative is this enlightened man?

I believe that the economics of the N.H.S. will soon compel the Government to introduce at least some charges as a way of raising more money outside taxation. Apart from this, my plea is based on quite simple human reactions. No one really values anything he gets (apparently) for nothing. My second point is that some element of direct payment increases a sense of responsibility that has been one of the major casualties of the N.H.S. And it should not be difficult to devise ways of exempting children, old-age pensioners, and the derelict.

"The second 'bee' which I spy is your commonly held belief that there is some mystic quality in the doctor–patient relationship which is cemented by money and destroyed by a salary." I think that here I have been misunderstood. My point—I hope I have made it—is that the direct payment of even a small sum at the time of consultation emphasizes the contractual relationship between professional man and client.

And I think that there is more behind it than this. The medical man, theoretically at least, has immense power. After all, he is, within limitations, supposed to have—in fact is licensed to have—power over life and death. I think that Donald Gould is right in thinking that desire for power is something that attracts men into Medicine. Subconsciously the patient needs to control this power with some magic of his own: money has all the appropriate symbolic force for this. And doctors don't really feel comfortable unless they have the accoutrements of power. They are not content with the simple life of the dedicated man. We may deplore this but we should recognize it as one of the facts of medical life.

My correspondent, writing as a "firm believer in the merits of family practice in the old-fashioned sense," says he is content with his lot. "But if I had any choice in my method of remuneration I would prefer to be salaried, and so would quite a few of my colleagues. Perhaps there ought to be a referendum." Well, I think there ought to be a referendum if enough people want it—or indeed if one really wants to discover *what* they want. But does one? Do they?

I know the limitations of working on a salaried basis. No employer of a salaried person can resist the temptation of seeing how cheaply he can obtain his services. And this oddly enough is accompanied by the delusion in the mind of the employer that he is a very generous person. With the State as almost the sole employer of doctors a universal salaried system would, I fear, be against the *financial* interests of the medical profession. If as doctors we want to keep up with the Joneses—and the Joneses are really very nice people—we should aim at being paid from as many different sources as possible. This is enlightened self-interest. (*To be concluded next week.*)

Letters to the Editor should not exceed 500 words.

Ophthalmic Graves's Disease

SIR,—In a recent leading article entitled "Ophthalmic Graves's Disease" (6 May, p. 329) it was stated that "lid retraction in Graves's disease is mainly due to spasm of the striated levator palpebrae superioris. . . . Increased sympathetic tone may also cause it. . . ." Mr. K. Wybar (24 June, p. 836) does not accept the role of spasm of the levator palpebrae because sympathicolytic drugs—for example, hexamethonium iodide—abolish the lid retraction in thyrotoxicosis. The observation that pharmacological amounts of sympathicolytic drugs can cause ptosis in such patients is not conclusive evidence that increased sympathetic activity is solely responsible for the lid retraction in Graves's disease. While I agree that many of the peripheral manifestations of hyperthyroidism can be attributed to sympathetic overactivity and can be reduced by sympathetic blocking agents, there is no clinical evidence of such overactivity in euthyroid patients with ophthalmic Graves's disease who show lid retraction, often unilateral.

Mr. Wybar also reiterates his previous argument[1] that he finds it difficult to reconcile spasm of the levator muscle with the finding of an increased fat content in the muscle in thyrotoxicosis. Crude estimations of fat content in a muscle do not necessarily correlate with its functional activity.

Pochin[2] has examined the mechanism of lid retraction in Graves's disease in considerable detail. In 12 cases of unilateral lid retraction unassociated with proptosis in Graves's disease he found clear elevation of the lower lid on the affected side in nine cases. He also showed that sympathetic stimulation in man causes lowering, not elevation, of the lower lid,[3] whereas elevation of the lower lid relative to the cornea was found when the upper lid was retracted by levator spasm or in Graves's disease. The pupil on the affected side is not dilated in cases of unilateral lid retraction in Graves's disease, and protagonists of the sympathetic theory of lid retraction must fall back on the assumption of differing thresholds for pupil and lid to sympathetic stimulation, though there is no good evidence for this.

Mr. Wybar states that "there is certainly no consistent evidence that a paresis of elevation of the eye in other conditions is associated with the phenomenon of lid retraction. . . ." In 1927 Collier[4] in an article entitled "Nuclear Ophthalmoplegia, with Special Reference to Retraction of the Lids and Ptosis and to Lesions of the Posterior Commissure," described examples of retraction of the upper lid caused by lesions in the region of the posterior commissure of the mid-brain, often associated with ophthalmoplegia, especially of upward gaze. The underlying disorders were variable—tabes, multiple sclerosis, vascular, degenerative, neoplastic, and encephalitic lesions of the brain stem all having been responsible. Mr. Wybar also mentions that myopathic as distinct from neurogenic lesions causing ophthalmoplegia seldom result in any significant innervational disorder. Several workers have commented on lid retraction in patients with myasthenia gravis[2,4] and in one case[2] the retraction of the upper lid and elevation of the lower lid and ophthalmoplegia improved following neostigmine therapy. Rundle[5] has also provided evidence for the close association between the paralytic variety of lid retraction in Graves's disease and superior rectus function. In certain patients with limited elevation and lid retraction the latter is abolished by directing the gaze downwards.

While I have stressed the evidence for the role of the striated levator palpebrae in the mechanism of lid retraction, I would agree with Mr. Wybar that overaction of the smooth palpebral muscles of Müller may also play a part. I think further investigations of the pathogenesis of the ocular manifestations of Graves's disease are required before we become too involved in speculative arguments.—I am, etc.,

REGINALD HALL.

Mental Health Services for Children

SIR,—Your thoughtful leader (3 June, p. 585) raises many important points which indicate the complexity of the subject. Custom encourages the use of "mental health" but Vickers[1] has observed that often the term means "mental ill-health." Both from experience of general practice and of child psychiatry I am aware of the need for more beds and units—some of this need must be met if only to lighten the load and lessen crises in children's departments—yet I would question your emphasis on the lack of psychiatric training, which is put forward as the most urgent aspect in a mental health service for children. To suggest that others are just waiting for psychiatric opinion (often equated with psychodynamic formulation) and are lost without it is to misjudge the situation and the skill of doctors and others dealing with children in trouble.

Indeed, the most significant part of your leader would seem to be contained in the following words: "it is often a matter of chance whether serious emotional disorder in children is treated within a medical, social, educational, or judicial framework." This fact is not merely a cause for lament but an opportunity for research. How many children are treated or dealt with, in which category, by whom, and with what results?

My own impression is that intervention in the total family situation often helps enormously. The psychiatric role is an adjuvant and excipient, with psychotherapy for the child being the least of the burden. Research must be directed not merely within the psychiatric context. Here child psychiatry has not merely a contribution to make, but also a lesson to derive. It must be seen against the limitations of psychiatry generally. The boundaries of psychiatry must be closely examined by those who would advance its claims. The emphasis on "mental health" as if it were indeed the obverse of "mental illness" has led to the prominence of concepts which only sometimes seem to have relevance to the larger field.

Possibly the Seebohm Committee will cast light on the role of the family doctors in the family service which must embrace medico-social factors affecting the mental health of children—and their families. The problem is administrative as well as partly training. In addition to the supportive functions which you stress, and only some of its present commitments, psychiatry can possibly assist most by helping to formulate some of the questions and evaluate the results.—I am, etc.,

Carcinogenic Properties of Ortho-dianisidine

SIR,—It was mentioned in the "Medical News" column of the *B.M.J.* (31 December 1966, p. 1663) that ortho-dianisidine was now to be subject to official regulation owing to its suspected carcinogenic properties. This chemical is used routinely in laboratories and hospitals in the glucose-oxidase technique. We therefore wondered what "medical tests" were thought necessary, since many of us using this technique have been pipetting 1% solutions of *o*-dianisidine in alcohol by mouth daily for some years now, while being unaware of its suspected carcinogenic properties. We should also be interested to know exactly what the evidence is which has incriminated ortho-dianisidine.

We feel that the answers to these questions would be of great value if brought to public attention in your columns, since in our experience those engaged in research seem quite unaware that there is any hazard involved in the use of ortho-dianisidine or tolidine.—We are, etc.,

Local Government Reform and the Health Services

SIR,—I was interested to read Miss Elizabeth Burney's article (1 July, p. 41). She does not seem to want to preserve the medical officer of health. Having neatly whittled down his duties, she then calls what remains "a hodge-podge of sanitary and statistical responsibilities." She entirely forgets that the majority of medical officers of health are appointed principal school medical officers, and has thus conveniently neglected this important branch of preventive medical care.

In the last paragraph the statement is made that "More scope could be given to professional administrators to obtain top jobs in the community health services for which the medical profession is not necessarily more suited than any other." On the basis that "health" is defined as a state of total mental, social, and physical well-being and not just an absence of disease, one wonders who are these "others" who are going to guide the community health services. Presumably the social worker can deal with the social problems and the psychiatric social worker with the mental problems, but outside the medical and nursing professions are there any good professional administrators who can really evaluate the priorities for the total social, mental, and physical health of the community?

It takes time and a great deal of expertise to learn how to run the community health services, and the last person we would want in charge is an economist who is always thinking how to save the rates. Miss Burney writes, "Whether there would still be anybody called the medical officer of health, or what his status would be, matters very little." Already there is a good deal of disenchantment from doctors in the present medical services. They have been cut out of the Review Body and have been told by the Management Side of the Medical Whitley Council that they are administrators first and doctors afterwards. It would be as well if some of those who plan the health services of the future would travel to the industrial areas and see how much clinical work is actually being done in the preventive medicine field. Of course we must accept change in the future, and it is likely that the family doctor will take over some of this work, but it will not happen very quickly unless the under-doctored areas receive a new influx of family doctors. The situation at present is not too grim in the county boroughs, but in the northern industrial county districts the writing is already on the wall, and there are very few junior doctors in the preventive medicine field. The immunization figures will fall; the screening for disease and the study of the epidemiology of disease will be reduced or non-existent; and the school health service (not mentioned in Miss Burney's article) will become no service at all. There are many other health tasks which will no longer be properly evaluated throughout this country.

My final advice to Miss Burney is that, before she renders the medical officer of health redundant by 1975, she makes sure that there is someone to put in his place. There is no very great evidence at present, particularly in the industrial areas, that these fine, non-medical, professional administrators really exist who can staff the top jobs in the new community health services.—I am, etc.,

Idiopathic Haemochromatosis

SIR,—Your leading article (25 February, p. 446) and Dr. W. H. Crosby's letter (20 May, p. 507) indicate the varying practice in the management of the first degree relatives of patients with idiopathic haemochromatosis and also underline our uncertainty of the natural history of the disorder in affected relatives. Some apparently believe that "all affected relatives should be treated by multiple venesections" while others reserve such therapy "for those with histological evidence of tissue damage as well as siderosis."

"Affected" relatives may be detected by measurement of the serum iron and serum total iron binding capacity (T.I.B.C.), by estimation of iron absorption, by hepatic biopsy, or by quantitative tests of total body iron storage using iron-chelating agents. Hepatic biopsy permits an estimation of the amount of excess storage iron and this is usually graded arbitrarily—for example, 0 to 4.[1] Relatives with grades 0 to 1 iron storage in the liver have normal iron stores.[2 3] Those with grade 2 iron deposition have approximately 2 g. of storage iron as measured by repeated venesection[4] and, we believe, should be observed without therapy unless serial biopsies or chelation tests reveal evidence of increasing iron storage. We have observed several such patients for up to five years without evidence of increase in iron storage (unpublished data). Relatives with grades 3 or 4 iron deposition on liver biopsy usually have 10 g. or more of excess storage iron[4] and, we believe, should be treated by venesection therapy irrespective of the presence of tissue damage, since such iron loading usually antedates the development of hepatic fibrosis.[5]

In our experience quantitative tests of iron storage using diethylenetriaminopenta-acetic acid allow more exact assessment of the degree of excess iron storage than does liver biopsy, and serial tests provide a more useful guide to the effect of therapy than do the serum-iron, T.I.B.C., or the haemoglobin concentration.[4]—I am, etc.,

Pressurized Aerosols in Asthma

SIR,—We have been interested in the recent correspondence (10 June, p. 699) dealing with bronchodilator aerosols, particularly those containing adrenaline, isoprenaline, or orciprenaline as the active component. Many writers have inferred from clinical observations that this form of bronchodilator therapy is contributing to a proportion of unexpected deaths among asthma sufferers. This has generally been attributed to the cardiac actions of these sympathomimetics. Much of the evidence that has been advanced to implicate these sympathomimetic amines as the cause of sudden death in asthmatics who have used them is anecdotal, and has been strongly criticized by others who have noted no incidence of fatalities directly attributable to these amines. The reports of clinical attempts to study this problem[1-4] are welcome.

As laboratory pharmacologists, we have undertaken some investigations on this subject, using animal experimentation. One aspect of our investigations was prompted by the suggestion that the interaction between large doses of sympathomimetics used as bronchodilators may promote deleterious cardiac effects. A considerable amount of work has been done on blood-pressure effects of large doses of these drugs, and of the interactions between them. With a single drug, or with combinations of them, long-continued administration leads to the development of tachyphylaxis. Our observations of their cardiac actions indicate that they follow the same pattern.

In experiments in cats infusions of adrenaline, isoprenaline, or orciprenaline were given over considerable periods of time at gradually increasing rates. This was done to mimic the possible effect of excessive use of aerosol preparations. In these experiments we have detected no sign of cardiac toxicity. In fact after the infusions had continued for some time the tachycardia which was produced initially by all three drugs declined despite increases in the rates of infusion. This development of tachyphylaxis (or tolerance, or resistance, to give alternative names which may be more familiar to clinicians) to the cardiac actions of the three sympathomimetic amines probably diminishes the risk of cardiac toxicity arising from their use. Furthermore, the effects of single intravenous doses of any one of these drugs during the continuous infusion of another were less the longer the duration of the infusion, indicating that the tachyphylaxis was crossed. This finding does not support the contention that the interaction between sympathomimetic bronchodilators may lead to an increased risk of cardiac toxicity.

The details of these investigations will be published elsewhere. In reporting this brief summary we wish to ally ourselves with those who seek to provide a basis of fact about the possible risk of sympathomimetic amines in asthmatics and to detract from the uncritical acceptance of clinical impressions.—We are, etc.,

SIR,—Recent correspondence in your columns concerning the side-effects reported in patients with asthma after excessive use of aerosol bronchodilators is of widespread and general importance (6 May, p. 375, and 10 June, p. 699). Likewise the importance of the comment from the Committee on Safety of Drugs Publication No. 5 in the Adverse Reactions series drawing attention to the dangers associated with overdosage of pressurized aerosols has been emphasized by its reproduction in "Today's Drugs" (1 July, p. 37).

The problem really is why do so many asthmatics use such large amounts of bronchodilators ? I have no doubt that the answer is simply that the vast majority of patients have never been properly instructed in the use of these aerosols ; although some pharmaceutical firms issue instruction notes on their use, these notes are often understandably inadequate, as frequently only actual demonstration and personal instruction will suffice for many patients. Indeed, the number of patients whom I see in my clinic for the first time already using one of these aerosols who have been correctly instructed in its use is usually very small. It takes only about five—or perhaps ten—minutes of careful instruction to teach a patient how to use an aerosol.

It is known from a number of clinical trials that one activation will usually produce a sufficient dose of bronchodilator to achieve significant relief of bronchospasm. There is no evidence to suggest that the degree of response is directly proportional to increasing the size of dose. Therefore several puffs in quick succession which fail to relieve bronchospasm almost certainly do so because the agent is not being fully inhaled into the bronchial tree, but is probably being absorbed through the buccal or upper respiratory tract mucosa. Under these circumstances large doses can be absorbed with the possibility of developing the now well-known toxic effects without achieving relief of the bronchospasm. It cannot be too strongly emphasized that persons using pressurized aerosols should be properly trained in their use, and instructed that if no relief is obtained from one or two actuations at an interval of not less than one minute no further relief should be expected from additional activations of the aerosol, and other assistance should be sought.—I am, etc.,

Leeds. GORDON EDWARDS.

Nebulizers

SIR,—I should like to thank Dr. B. M. Wright (20 May, p. 508) for his information regarding the details of evaluating the performance of nebulizers. However, for routine testing by untrained persons I would suggest that the method I described, with the flow meter between the cylinder and the nebulizer, should be adopted—this in fact being the way in which the nebulizer is used in the treatment of patients.—I am, etc.,

Typhoid Fever—30 Years On

SIR,—I read with much interest Dr. J. M. Morfitt's letter in your journal (24 June, p. 839). An almost identical epidemiological parallel was discovered in Edinburgh during 1965 when typhoid fever occurred in a 65-year-old housewife 31 years after her husband had typhoid, and who had subsequently remained an unknown intermittent urinary carrier. A report of this episode, which threw further doubt on the reliability of the Vi agglutination test for the detection of chronic typhoid carriers and also demonstrated shortcomings in the Food Hygiene (Scotland) Regulations,[1] was recently published under the title "Typhoid Fever—Thirty Years After."[2]—I am, etc.,

Human Vibriosis

SIR,—The articles on human vibriosis by Dr. W. D. White, and by Dr. J. H. Darrell, Mr. B. C. Farrell, and Dr. Rosemary A. Mulligan (29 April, pp. 283 and 287) were of great interest to us. We should like to record a similar case seen at this hospital a few months ago.

A 5-month-old girl was admitted with a history of convulsions. On examination she was pyrexial, with a temperature of 106° F. (41° C.), with marked dehydration and peripheral vascular failure. Generalized twitching was present, and the abdomen was slightly full. The results of investigations were as follows: Haemoglobin 13.3 g./100 ml., P.C.V. 41%, W.B.C. 19,000, N. 8%, L. 68%, M. 20%, metamyelocytes 4%. The film was suggestive of a severe toxic process. Serum Na 138 mEq/l., K 6.3 mEq/l., HCO 10 mEq/l. (the blood culture findings are detailed below). Cerebrospinal fluid normal. Rectal swab negative for *Staphylococcus aureus*, *Shigella*, *Salmonella*, and specific *Escherichia coli*.

Despite intensive therapy with intravenous fluids, hydrocortisone, and chloramphenicol she continued to deteriorate and died seven hours after the onset of symptoms.

At post mortem (by Dr. G. A. Stirling) the jejunum and ileum were found to be inflamed and contained bloodstained watery faecal material. A segment of ileum, 12 cm. long, was dark in colour, suffused with blood, and appeared necrotic. The mesenteric vessels were patent. The appendix was healthy, but the mesenteric lymph nodes were enlarged. The caecum was congested, but the remainder of the colon and the rectum appeared normal. The peritoneum was congested and there was a small amount of brown fluid in the peritoneal cavity. The lungs were collapsed and there were a few petechial haemorrhages in the pleura, pericardium, oesophagus, and gastric mucosa. The remaining organs showed no abnormalities apart from slight fatty change in the liver, and some oedema of the brain.

Microscopically the gastric, jejunal, and ileal mucosae were infiltrated with acute and chronic inflammatory cells ; no specific features were noted. The colon appeared normal. The lungs showed interstitial pneumonia in some areas. Acute fatty change was apparent in the liver and tubular degeneration in the kidneys.

An organism similar to that described by Dr. Darrell and co-workers was isolated from the blood culture bottles ("liquoid" broth) after 48 hours' incubation anaerobically, and in 10% carbon dioxide. It appeared as pin-point transparent colonies on the blood agar plates subcultured from the "liquoid" broth and incubated overnight anaerobically and in 10% carbon dioxide. Growth on the carbon dioxide plate was more profuse than on the anaerobic, and none appeared on the aerobic plate.

The organism stained easily by Gram's method and appeared predominantly as Gram-negative spirals with lesser numbers of curved rods. Subculture proved difficult, but best results were obtained on sloppy blood agar slopes incubated in 10% carbon dioxide. This vibrio was oxidase- and catalase-positive and grew at 42° C., thus falling into the group of "related vibrios." It was resistant to penicillin but sensitive to tetracycline, chloramphenicol, and erythromycin on disc testing. Mr. Moylan Gambles of the Central Veterinary Laboratory, Weybridge, kindly confirmed the identification and considered this organism to be closely related to *V. coli*.

It is difficult to assess the significance of the isolation of this vibrio, but the absence of other findings and the similarity to cases described in the U.S.A.[1] suggest that this infant was suffering from vibrionic enteritis. Our post-mortem findings resemble those of Lochte[2] on an adult from whom a "related vibrio" was also isolated.

We should like to thank Dr. M. J. Wilmers and Professor A. C. Cunliffe for permission to publish this case.

—We are, etc.,

Integrated Training Schemes

SIR,—Mr. P. W. R. M. Alberti is to be congratulated on his article on integrated training schemes (8 July, p. 101). I am sure he is right to mention that any training scheme is dependent on the concentration of units into larger area centres, where there would then be sufficient S.H.O. and registrar staff for these schemes to be initiated. These teaching programmes must give not only adequate clinical and operative training but also instruction for the higher examinations ; and they must include the facility of rotation into other units, designed to broaden the trainee's experience within his specialty. In these enlarged centres there would be sufficient consultant staff to allow the development of special interest in subsections of the specialty, in addition to routine work, to give a comprehensive training programme. For instance, in E.N.T. three of these subsections might be special otology, soft-tissue neck surgery, and audiology. The last two in this respect have been sadly neglected in a specialty which until recently has run the risk of becoming excessively ossific-centred.

In suitable units Mr. Alberti mentions G.P. clinical assistant participation. I would suggest that for these appointments and for the greater specialization that will in itself result within large group practices there could be courses for general practitioners in area specialty centres. Finally, both these training schemes hinge, in my opinion, on available senior registrar staff, who would be able to participate in these training schemes as well as deal with some of the clinical and operative work of their various chiefs. I feel it is this grade of doctor who should be rotated to include central establishments, where their training would include further facilities for teaching and a discipline for research. I only hope that Mr. Alberti's timely reminders will be heeded by those who are now deliberating specialty training at central level.—I am, etc.,

Middlesbrough. M. HOROWITZ.

SIR,—I must take issue with Mr. P. W. R. M. Alberti on some points in his article (8 July, p. 101).

(1) "If training is to be centred about large institutes, then inevitably there will be no juniors in the periphery. This need not be a bad thing, and in many instances will only stabilize an already current situation." This takes no account of potential general practitioners not normally requiring integration in training schemes for specialists, and for whom there is no room in larger centres. Why should they not work in peripheral hospitals under adequate supervision by the larger number of consultants Mr. Alberti rightly favours ?

(2) "Some services will be centralized . . . as communications improve so the need for small isolated units will diminish." Public service communications are in fact deteriorating, not improving: patients who are not car owners are already finding difficulty in attending hospital from remote country districts.

(3) "Hospitals might therefore be built where they can be manned, rather than where political pressure dictates." They should be built where they are needed following political pressure exerted on the Government by local M.P.s etc., endeavouring by their good reputation to attract junior staff to work there.

(4) "Consultants and general practitioners will have to work much closer together." How ? General practitioners are already too few and overworked (a fact recognized by the Minister and by the last Review Body's recommendations). Married women graduates might be encouraged to do a little more, but medically qualified mothers of small children cannot provide a substitute for the thousands of junior staff the "large institutes will siphon off from the periphery," and who do so much of the routine and emergency work, especially at night.

I could say a great deal about rotating schemes, much of it highly critical, but Mr. Alberti and I agree they should not ideally require change of residence. I doubt whether this is so important if there are absolutely no unnecessary expenses or *unexpected* removals.

Finally, I agree warmly with Mr. Alberti's strictures on the requirements for higher degrees and the Colleges' approval of undesirable posts as suitable for training. I share his feelings that at present specialist training is far too haphazard, and that a shorter organized course of training may mean harder work during that time but at least could be linked to the very high probability of a consultant post in the future, owing either to retiral of an older man or to the creation of a new post planned years in advance from statistical forecasts already available to the Ministry if it would but seek them.—I am, etc.,

Oculogyric Crises Due to Phenothiazines

SIR,—During the past year I have seen three young people with oculogyric spasms which I considered to be caused by phenothiazines. Two of these patients were seen during the past week.

The patients were aged 15, 19, and 21 years. All presented in the same way, with oculogyric crises and hyperextension and rotation of the neck recurring every few minutes and accompanied by persistent mydriasis.

The first two patients were suffering from subtertian malaria, and were being treated with chloroquine. Prochlorperazine (Stemetil) was given in each instance because of vomiting. In the first patient, a girl of 15, the spasms started after two doses of 10 mg. Pentobarbitone (Nembutal) 100 mg. was given by mouth, and the attack ceased after about an hour. The second patient, a 19-year-old male, was given prochlorperazine 5 mg. at midday on the day of admission, then 12.5 mg. intramuscularly at 4 p.m. the same day, and repeated on the following day at the same time. Spasms started at 6 p.m. and continued for an hour after giving pentobarbitone 200 mg. The third patient, who was suffering from infectious hepatitis, was given perphenazine (Fentazin) 4 mg. on admission to hospital because of vomiting, and this was repeated the following afternoon. Spasms commenced two hours later. He was given 150 mg. pentobarbitone, following which spasms persisted for about an hour.

These cases are reported to emphasize the risk of using phenothiazines in young people. Jaundice might be expected to potentiate this drug effect, and it is suggested that malaria, chloroquine, or both might do likewise.—I am, etc.,

National Kidney Centre

SIR,—In view of recent press reports about the closure of the National Kidney Centre I feel constrained to use your columns to place on record a fuller statement of the reasons for closure of the National Kidney Centre on 1 July 1968.

The National Kidney Centre was set up in November 1966 as a non-profit-making charitable trust with its sole aim to determine whether the rate of expansion of home dialysis with a minimum of medical support could be achieved in the British Isles. It was never intended to compete with the National Health Service, as has been suggested, and indeed it was hoped from the outset that the centre would be able to co-operate with the N.H.S. dialysis programmes wherever possible, to ensure the advancement of this form of treatment. Unfortunately the official attitude of the Ministry of Health has prevented any official co-operation with N.H.S. dialysis units.

To date the centre has been responsible for the training and subsequent maintenance in the home of 27 British nationals and four non-British nationals, utilizing the staff of one doctor and three trained nurses. No hospitalization requirements with dialysis have been necessary during the nine months of its function, and all patients are in good health. The feasibility of expanding home dialysis with integration into existing local community dialysis facilities from a specialist training centre has been successfully demonstrated in the United States.

However, its present failure in this country has not been due to shortage of funds or resources but simply to the inability to find a suitable formula to bridge the dogmatic distinction separating medical practice inside and outside the N.H.S. Full details of the results obtained and methods used will be published in due course. A preliminary report is in the press.[1]—I am, etc.,

London N.3.
STANLEY SHALDON,
Medical Director,
National Kidney Centre.

Psychological Factors and Ulcerative Colitis

SIR,—I was delighted to read your leading article (1 July, p. 1) and the paper by Dr. F. Feldman and colleagues (p. 14) on psychiatric studies of patients with ulcerative colitis. I have long ceased to believe in the concept of "psychosomatic medicine," which in my opinion is a confession of ignorance on the part of the profession regarding the aetiology of these conditions.

The concept that a disease such as ulcerative colitis, with its intractable diarrhoea, blood loss, and exsanguination of the patient, could be psychogenic in origin has always appeared to me to be utterly absurd. Recent advances in medical treatment such as steroid therapy and salazopyrine and such successful surgical procedures as colectomy for the removal of the diseased area of bowel have confirmed my belief that the psychosomatic approach is wholly wrong. The spectacle of these severely ill people being subjected to extensive psychotherapy seems to me the negation of all common sense, especially in the light of the new knowledge we now possess in treating this condition. It is equally true with other so-called psychosomatic illnesses, which will no doubt prove to have a physical basis on further investigation.

I note that Dr. Feldman and his colleagues conclude their very comprehensive investigation by stating that there is now a "central problem of whether primary psychosomatic disease exists, and, if so, how it can be explained." I submit that this conclusion is a victory for common sense and that the whole theory of psychosomatic medicine should be subjected to a thoroughgoing analysis, to see on what scientific basis its theories rest.—I am, etc.,

Hornchurch,
Essex.
D. D. COWEN.

Unexpected Foreign Body

SIR,—Dr. G. B. Stein (1 July, p. 51) raises an important matter—the difficulty arising in making a diagnosis when a non-opaque denture has been inhaled—and has a point in suggesting that they should not be allowed to be made.

However, among the innumerable objects which are accidentally inhaled there are many that are radiotranslucent or so small as to be easily missed. Dr. Stein's case report, like several previous reports, including my own,[1] serves to remind us that should a patient who has been unconscious subsequently develop pulmonary symptoms the possibility of a foreign body being present should always be in mind, and that lack of radiological confirmation is no guarantee that one is not present. When real doubt exists the patient should be referred for bronchoscopic examination.—I am, etc.,

"Swallowed" Endotracheal Tube

SIR,—The report by Mr. J. A. S. Dickson and Mr. G. C. Fraser (24 June, p. 811) of five cases of neonatal endotracheal tubes acting as foreign bodies in the oesophagus is of considerable interest. These infants recovered from neonatal asphyxia despite failed endotracheal intubation. How many others are subjected to this procedure unnecessarily?

It seems to be a current fashion that the diagnosis of neonatal asphyxia demands that an immediate attempt should be made to intubate the trachea. I am sure this is a wrong approach. This aggressive attitude may be harmful to the infant in three ways. Firstly, because the attempt can actually delay oxygenation of the blood, not only by wasting valuable time but also by mechanically obstructing an otherwise effective gasp. Secondly, it may produce reflex inhibition of respiration. Thirdly, even relatively experienced resuscitators cannot always avoid soft-tissue damage. Add to this the more bizarre complications, such as those cited in the report, and it ought to be obvious that intubation of an infant's trachea should not be undertaken without good reason. Failure to respond to oxygen properly administered by bag and facemask[1] (or the Samson[2] or Cardiff[3] resuscitators) in the correct extended position, preceded by careful toilet of the nose and pharynx, might be a justifiably good reason. The mere diagnosis of neonatal asphyxia in itself is not.—I am, etc.,

Wrotham, Kent. J. V. I. YOUNG.

Urinary Infection Presenting with Jaundice

SIR,—We have read with interest the article "Urinary Infection Presenting with Jaundice" by Drs. A. B. Arthur and B. D. R. Wilson (4 March, p. 539). This prompts us to report a case of our own.

A female infant born prematurely (birth weight 1.4 kg.) has been in hospital since birth and survived seven severe infections in the first seven months of life. These were: omphalitis (*Staphylococcus aureus haemolyticus*), rhinitis, bronchitis (*Pneumococcus*), bilateral otitis media (*Proteus vulgaris*), rhinitis, sinusitis maxillaris (*Proteus vulgaris*), pyelonephritis (*Escherichia coli*), bronchopneumonia, bilateral maxillar sinusitis (*Staphylococcus albus*), and enterocolitis (*Escherichia coli* $O_{111}:B_4$).

The fifth of these infections, pyelonephritis, which she had at 3 months of age, was associated with jaundice. The total serum bilirubin was 8.7 mg. per 100 ml. (direct van den Bergh 4.2 mg./100 ml.). The other infections which this child had were by no means less severe, and caused by a variety of organisms, yet only the pyelonephritis was associated with jaundice. This seems to support the view put forward by Drs. Arthur and Wilson.—We are, etc.,

Drug Treatment Centres

SIR,—The statement in your leading article (20 May, p. 455) that "numerically small are the methedrine and L.S.D. users, the chlorodyne drinkers, glue sniffers, and people dependent on barbiturates" is probably correct for the younger age groups if one excludes the abuse of the Drinamyl type of drug (although methedrine and L.S.D. are both becoming increasingly popular). As regards the middle-aged, however, barbiturate dependence can by no means be regarded as a numerically small problem, and in that age group it is second only to alcoholism. Barbiturates are prescribed in enormous quantities, increasing year by year—for example, from 15 millions in 1961 to over 17 millions in 1965. This makes them readily available agents for overdosage, and the steady rise of barbiturate deaths by suicidal and accidental overdosage in previous years[1-3] is still continuing—from about 515 (suicide) and 140 (accident) in 1956 to approximately 1,490 and 525 respectively in 1965. Among nonfatal suicide attempts barbiturates are the most widely used agent, accounting, for example, for 60% of admissions for suicide attempts to various general and psychiatric hospitals in a personal study carried out a few years ago.[2] In a recent Australian study Drs. F. A. Whitlock and J. E. Edwards (27 May, p. 576) found that barbiturates were the agents employed in approximately four out of five cases of "impulsive" suicide attempts. Just as drunkenness is relatively more common among alcoholics than among social drinkers so the risk of barbiturate overdosage affects chiefly (though of course not exclusively) those taking the drug regularly to excess (and hoarding supplies).

Locket[4] estimates that 4–6% of all cases of acute barbiturate poisoning admitted to his unit were barbiturate addicts. Thus the high number of people dying from or admitted for acute barbiturate poisoning probably reflects the prevalence of barbiturate dependence, chiefly among women. This conclusion is supported by findings such as that among 38 female drug addicts (almost all middle-aged) admitted to the St. Bernard's unit in 1962–3 there were 10 barbiturate addicts and 11 more dependent on Drinamyl,[5] and of 69 female addicts admitted between 1962 and 1964 (by then an increasing proportion of young amphetamine and heroin-cocaine addicts were admitted) a minimum of 29 were dependent on barbiturates.[6] During 1966 alone, outside hospital, I saw 23 barbiturate addicts, but it is only quite recently that I came across a youngster who had sniffed glue regularly for a few weeks when he was unable to get hold of other drugs. Although a few youngsters mention that occasionally they had temporarily tried glue sniffing without much "reward," in this country this form of drug abuse seems to be quite rare and can surely not be placed "numerically" or in any other aspect of importance alongside barbiturate dependence.

Barbiturate abuse and addiction must not be overlooked when at present it is mainly the young amphetamine, cannabis, and heroin-cocaine abusers who make headlines; and all too often one comes across barbiturate addicts who have been investigated for a long time for "epilepsy" without having ever been questioned about their use of barbiturates and the possibility of withdrawal convulsions. —I am, etc.,

Liquor Bilirubin Levels

SIR,—I note with some interest the correspondence by Dr. A. F. Fleming on liquor bilirubin levels (24 June, p. 840). As he states, there are both chemical and spectrophotometric methods in use at the present time for the estimation of bilirubin in liquor amnii. He goes on to point out the difficulties of these methods and the likely sources of error and finishes with an appeal for a quantitative method which expresses the results in terms of µg. of bilirubin and not as a ratio or optical density measure.

A method developed in this hospital[1] does, I believe, satisfy many of the objections which Dr. Fleming raises, in that it uses the extreme solubility of unconjugated bilirubin in chloroform as a means of extracting this substance from liquor. Reduction of the chloroform volume brings about a fourfold concentration of the bilirubin. By the use of the spectrophotometer and a standard curve, the quantity of bilirubin present can be measured in terms of absolute units. The method is simple to carry out, and if one wishes to express the result as µg. of bilirubin per mg. of protein, as Fleming suggests, this could be easily done. Using this method we have examined over 120 samples of liquor. With one exception there has been an extremely good correlation between liquor bilirubin and foetal condition. These results will be published in due course.—I am, etc.,

Ehlers–Danlos Syndrome

SIR,—In my article on the heterogeneity of the Ehlers–Danlos syndrome (3 June, p. 612) I suggested that spontaneous rupture of large arteries occurs only in patients with a distinct "arterial" type of this syndrome, and I also stated that I intend to publish a separate article on this "arterial" type of the Ehlers–Danlos syndrome.

In their letter about my findings Dr. S. G. Elkington and Dr. P. H. Beighton (24 June, p. 843) claimed that all patients with Ehlers-Danlos syndrome should be regarded to be at risk through arterial bleeding.

To reply in full to all the points raised by your correspondents I would have to write almost the whole of my as yet unpublished paper. In brief, our disagreement, if any, seems to stem from the fact that they refer to "the risk of arterial bleeding" while I wrote about "*spontaneous* rupture of large arteries." Our interpretation of some of the published reports on arterial complications in Ehlers–Danlos syndrome also differs, because, unlike them, I find it impossible to identify the clinical type of the syndrome in the patients described.—I am, etc.,

A. P. BARABAS.

Infant-scalp Vein Needles

SIR,—At least 18 months ago house-officers at the Royal Victoria Infirmary, Newcastle upon Tyne, started to use these little sets in circumstances where rapid intravenous infusions are unnecessary—for example, in maintenance electrolyte therapy and in the slow administration of low-molecular-weight dextrans. If the needle blocks, as it commonly does after two or three days, it may be quickly and relatively painlessly changed; a quiff of cotton-wool and a squirt of Nobecutane hold it in place.

Perhaps because of this usually short life of these needles "chemical" phlebitis is uncommon. Most infusion needles are still too irritative. In a recent unpublished survey conducted by two colleagues and myself the "complication" rate—that is, phlebitis, cellulitis, leakage, and thrombosis—reached 50% in the case of certain plastic cannulae. An early warning sign of phlebitis is a sharp squeak of protest from the patient when the infusion is suddenly speeded up.

The removal of a drip needle from a severely inflamed vein is often followed by thrombosis, and was perhaps the situation encountered by your correspondent (1 July, p. 48). If, as the needle is withdrawn, 1–2,000 units of heparin and 10–25 mg. of hydrocortisone are injected thrombosis is often prevented and the vein saved for another day—or night.—I am, etc.,

M. L. SNAITH.

Derbyshire Royal Infirmary,
Derby.

Diet and Diverticulitis

SIR,—I find it difficult to understand the apparent criticism of the letter of 2 July 1966, p. 50, by Dr. T. L. Cleave and myself, relating diverticulitis to the consumption of refined carbohydrates, as contained in the letter of Dr. E. H. Goulston (6 May, p. 378). He agrees that no case of diverticulitis has ever been reported from Ethiopia, where it is known that the grain eaten consists mostly of teff (a kind of millet) taken unrefined, but refers to the infrequent occurrence of diverticulosis. If diverticulosis has been seen at Addis Ababa this is exactly what one might expect, because in that capital considerable amounts of white flour are now being consumed,[1] and we should expect cases of diverticulitis to follow in due course, as happened in the American Negro people referred to in our letter. For, in conformity with my own "rule of 20 years," advanced after observing the length of time spent in towns by Zulus before they develop diabetes, as set out in our joint work,[2] it would seem that a definite period of time is also needed before a refined diet can lead to overt diverticular disease.

Dr. Goulston asks if barium enema studies have been performed on Zulus. I am happy to supply the following recent figures for such examinations:

Urban[3]	King Edward VIII Hospital, Durban.	218 Barium enemas	4 cases of diverticular disease.
Rural[4]	Eshowe and Empangeni Hospitals in Zululand.	100 Barium enemas	No case of diverticular disease.

Though these figures are significant at the 5% level, I should like a still larger series; even so, these results certainly indicate that diverticular disease is emerging precisely as was observed in the American Negro people, as mentioned in our letter.—I am, etc.,

G. D. CAMPBELL.

I.V.P. in Renal Colic

SIR,—The value of this measure is admirably assessed by Mr. James A. Rhind (1 July, p. 24), and even if some night radiography is entailed there is more justification for doing it than in much of the radiography at present carried out at night as "emergency." Immediate I.V.P. in renal colic usually provides a conclusive diagnosis, a good guide to management, and a baseline from which to assess if conservative methods are adopted.

I too have observed therapeutic effect, due presumably to the diuretic effect of the contrast. When this happens pain can be severe, and ready analgesia should be available if patient control on the *x*-ray table is to be maintained. The amount of ionizing radiation used by this technique is not likely to be in excess of what would be used in "cold" investigation, especially as single-film pyelograms usually suffice in interval-check examinations.—I am, etc.,

DAVID J. MITCHELL.

Royal Albert Edward
Infirmary,
Wigan, Lancs.

Chloroquine

SIR,—Recently Professor A. W. Woodruff, of the London School of Hygiene and Tropical Medicine, commented, in answering a query in the *Practitioner*,[1] that "It is now generally agreed that chloroquine should not be used as a prophylactic but should be reserved for the treatment of acute malarial attacks . . . unfortunately strains resistant to it have recently emerged and it is considered best to try to avoid encouraging the emergence of further resistant strains."

This is excellent theoretical advice, but how far is it applicable in practice? Many sources, official and non-official, in East Africa recommend chloroquine for prophylaxis because there is known to be proguanil–pyrimethamine resistance locally and as yet none to chloroquine. As a result I believe the majority of the prophylactic-consuming public takes a 4-aminoquinoline. For a small number of others to take proguanil helps the main problem but little and exposes them personally to the slight risk of a malarial attack.

If agreement is as general as Professor Woodruff avers—and the U.S. Army would seem another notable dissentient—then what we need is a massive campaign to depopularize chloroquine in the minds of very numerous doctors throughout the tropics, not to mention some malariologists. Failing this, the isolated informed voice will be crying in the wilderness and exposing the individual patient to slight risk on theoretical grounds which it is unfortunately too late to apply.—I am, etc.,

Appointments Systems

SIR,—Is is not high time that the idle pretence of an appointment system operating in hospitals should be dropped? I am tired of listening to the complaints of patients who have been given an appointment for a certain time and then have been kept waiting two or three hours beyond the appointed time. I send patients mostly to two teaching hospitals of deservedly high reputation and things are no different there.

I once telephoned an appointments clerk myself, and the charming young lady gave me a certain time for a patient. An hour or so later I telephoned again for another patient and I was given exactly the same time. When I pointed out that the consultant could not possibly see more than one patient at a time, I was met by the excuse that some patients do not turn up and "the doctor must not be kept waiting."

I have even had it reported to me by patients that 20 or 30 of them had been given the same time to attend. This seems to me pure deception. An appointments system which gives the same time to all the patients is no appointments system at all. Why then should it pretend to be? We might at least be honest and disclaim any pretence at an appointments system, that would at least be honest, but what happens now is pure humbug and deception.—I am, etc.,

London W.1.

A. J. HAWES.

Diabetes in the Tropics

SIR,—In his excellent paper on the above topic (17 June, p. 747) Professor S. R. A. Dodu stated that 20% of diabetic patients reporting for the first time to the Korle Bu Hospital in Accra confirmed their suspicions by "tasting their urine." May I mention yet another sign of glycosuria I have observed when several diabetic patients, reporting similarly in Sierra Leone, another tropical area, said they had noticed "many ants in their chamber pots the next morning"?—I am, etc.,

Plaistow Hospital, London E.13. A. F. TUBOKU-METZGER.

Portable Pharmacy

SIR,—I possess a portable pharmacy similar to that described by Dr. P. W. Mathew (3 June, p. 641). The measurements are 11½ × 8 × 10 in. (29 × 20.3 × 25.4 cm.). It is probably a hundred years old. Many are of greater antiquity.

One was offered recently at an antique shop in Towyn, North Wales, for £40. *Fama habet* that a leading London auctioneer sold the same article later for £600.

I trust that Dr. Mathew's box has a similar remote lineage.—I am, etc.,

High Wycombe, Bucks. G. S. W. EVANS.

Blood Pressure Monitoring

SIR,—It is at least 40 years since a medical practitioner in charge of an antenatal patient became ashamed if his patient's abnormal rise of blood pressure went undetected.

The report of Dr. W. E. Miall and Mr. H. G. Lovell (10 June, p. 660) raises the question of how long all patients are to wait before the medical profession comes to regard itself responsible for seeing that each patient has the blood pressure examined yearly, and if necessary an attempt made to return the blood pressure to the safe zone.—I am, etc.,

London S.W.19. AMY M. FLEMING.

Muscle Stiffness and Vitamin C

SIR,—With reference to the published findings of Drs. L. Corbett and A. Barr (8 July, p. 113) on muscle stiffness and vitamin C, I regret to note that the dosage scheme found effective by me had not been followed—namely, 500 mg. of vitamin C *in one dose* one hour before the unaccustomed exercise—and 400 mg. *in one dose* directly after it.—I am, etc.,

London S.W.7. I. H. SYED.

Folate Deficiency in the Elderly

SIR,—Attention has been drawn to this subject in the *B.M.J.* (10 June, pp. 652 and 670).

During a recent trial concerning the efficacy of total-dose infusion of iron dextran in correcting iron deficiency anaemia in the elderly[1] serum folate levels were estimated, using the method described by Spray,[2] on the patients before and six weeks following treatment. The patients' age range varied from 69 to 89, half being treated in the day hospital and half as in-patients. The serum folate range in 37 pre-infusion subjects was 1–19.7 mμg./ml. (mean 5.3; S.D. 3.4 mμg./ml.), and at six weeks post-infusion their range was 1.5–26 mμg./ml. (mean 4.6; S.D. 2 mμg./ml.). Six pre-infusion patients had values below 3 mμg./ml. and nine post-infusion patients had values below 3 mμg./ml. Twenty-eight patients with an initial serum folate level below 6 mμg./ml. had a mean haemoglobin of 61% (S.D. 11 mμg./ml.) and six weeks after treatment had a mean haemoglobin of 75% (S.D. 11 mμg./ml.), while nine patients with initial folate levels over 6 mμg./ml. had a mean haemoglobin of 65% (S.D. 8 mμg./ml.) and a post-treatment haemoglobin of 75% (S.D. 11 mμg./ml.).

Attempting to correct iron deficiency in the elderly by total-dose infusion of Imferon (iron dextran) does not seem to influence the serum folate levels of the patients concerned, and probably the initial serum folate level does not influence their response to iron dextran as judged by the haemoglobin rise. However, as serum folate levels probably do not accurately reflect tissue state, the diagnosis or exclusion of folate deficiency on serum folate levels alone appears unjustified.—I am, etc.,

Sliding Board for Severely Disabled Patients

SIR,—Now that the more severely disabled are able to drive, with the introduction of automatic gear change in smaller cars, greater independence can be obtained by the use of a sliding board. Whereas before it was necessary for tetraplegics to be lifted bodily into their cars, now they can transfer from wheelchair to motor car, if not entirely alone, with the minimum of assistance.

A "sliding board" has been developed by several tetraplegics and paraplegics at the Chaseley Trust for Disabled Ex-Servicemen at Eastbourne, and is made in their own workshops by them. It is constructed quite simply and cheaply from selected wood covered with Formica, which provides a smooth non-abrasive sliding surface. A small cushion may be placed under the buttocks as extra padding, but we find that the board is sat upon for so short a time that this is not usually necessary.

Although we have not tested the board among geriatric or other types of disabled patients, we feel sure that they too could easily benefit from it, and apart from use with the car it can also come in handy in the house to transfer from bed to chair, chair to lavatory, etc.

The ideal size was found to be 2 ft. 6 in. by 6 in. by ¾ in. (76 cm. × 15 cm. × 1.9 cm.). Further information about the sliding board can be obtained from Handcarved Signs, Chaseley, Southcliff, Eastbourne, Sussex.—I am, etc.,

MARY SEIFFERT,
Senior Physiotherapist,
The Chaseley Trust.

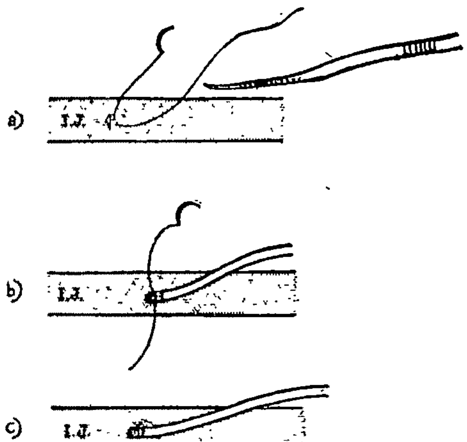
Eastbourne, Sussex.

Ventriculo-atrial Shunt for Hydrocephalus

SIR,—Ventriculo-atrial shunt procedure is now the commonly accepted treatment for progressive hydrocephalus in infants. It appears to be the common practice to tie the internal jugular vein over the venous catheter during the operation. Tying the internal jugular vein will result almost certainly in formation of a thrombus between the site of ligature and the beginning of the superior vena cava. This thrombus may be an important factor in causing septicaemia and in blocking the shunt mechanism.

It is quite feasible to insert a venous catheter in the internal jugular vein without tying that vein.

The internal jugular vein is dissected above the sterno-clavicular joint and two loops of thread (No. 40) are passed around it. The two loops are pulled apart to stretch the vein and a suture is placed in the vein wall between them using 4/0 silk on an atraumatic needle. This is left untied (see Fig). A small nick is made in the vein wall by sharp-pointed scissors just distal to this suture. The venous catheter is introduced through this and pushed in until the tip is believed to be in the atrium. The loose ends of the suture in the vein wall are now tied over the nylon ring in the venous catheter. If the nick in the vein wall is small enough no further sutures are needed. The scalp wound is closed next and the neck wound is closed last, after the loops of thread round the vein are removed.



Showing the technique of inserting the venous catheter into the internal jugular vein (I.J.).

The first two patients in which this technique was used are alive and well six months after the operation. There was no leakage of blood from the site of insertion of the venous catheter into the vein.

The venous catheters used were made by The Holter Company, Bridgeport, Penn., U.S.A., and the valves used were those made by Mr. Stanley C. Wade and Mr. Ronald Dahl for Mr. Kenneth Till.

Annual Representative Meeting

Sir,—May I, through the courtesy of your columns, express my protest at what occurred on the last day of the Bristol A.R.M.?

Very many of the motions down for debate under the heading "Hospital and Consultant Services" were glossed over, without debate or discussion of any kind, as a matter of expediency. Thus whole blocks of motions, at least two of which concerning distinction awards for consultants (501 and 608) contained important matters of principle, were accepted as references to Council without the Representative Body being given the opportunity to hear argument on both sides, so that the representatives' own views could be formed, altered, or augmented.

Why, when the Association claims to speak for all sections of the profession, was this allowed to happen? The short answer is that the Representative Body ran short of time. It ran short of time because some few Divisions were allowed a disproportionate length of platform time, endlessly discussing points of detail which should have been dealt with or referred to the appropriate committee.

I refer particularly to the debate on the new constitution, which time and again descended to the level of "Shall we have By-law No. so-and-so, Subsection C, paragraph 3, second sentence, first line, fourth word, or not." I also refer, however, to the debate on General Medical Services, much of which was concerned with detail, important in itself, but properly dealt with by the G.M.S. Committee in session, not by the Representative Body in debate.

It should be unnecessary to reiterate, but evidently it is, that the A.R.M. is concerned with matters of principle, and that it delegates detailed debate to the committees reporting to it. Perhaps the chairmen of the committees concerned, together with the chairman of the Agenda Committee, would note these strictures, so that in future years we as a Representative Body may be given the opportunity of discharging our duties adequately.—I am, etc.,

Casualty Department—or G.P. Service?

Sir,—The letter by Mr. B. J. Preston and his co-authors (1 July, p. 46) makes somewhat depressing reading, though their experience is probably typical of many hospital casualty departments in large towns.

Of the six categories of patient listed by Mr. Preston it would seem that only visitors to London (8% of his casual attenders) should be considered as eligible for casualty. Four of the other groups (more convenient to go to hospital; patient already attending the hospital for another condition; patient wanted a second opinion; and no general-practitioner surgery on that day) should not normally be accepted at casualty, though exceptionally those in the last group might be seen once and then referred back to the general practitioner. As to difficulty in registering with a general practitioner, there should be some reservation in accepting many of these patients' statements. Registration in central London can be difficult, but a fair proportion of such patients have simply been too feckless or thoughtless to bother about finding a general practitioner. This, indeed, is borne out by Mr. Preston's statement that 25% of all patients resident in that area (excluding visitors and those in transit) are not registered with a general practitioner. With certain doctors' lists as loaded as they are, and with the present miserable system of capitation, it is hardly surprising that some general practitioners are disinterested in collecting more "heads." Other doctors are understandably resentful that people, long resident in an area, often fail to register until they are ill.

The right answer to this problem is not to convert the hospital casualty department into a glorified health centre, but to take steps to ensure that general practitioners are encouraged to provide a proper service and that the public uses that service responsibly. At the present time there is increasing tendency for patients to bypass the general practitioner. It is virtually a daily experience for casualty doctors and nurses to be told by patients that they have "paid their stamps" and are "entitled to treatment." However much these mistaken beliefs may motivate a largely ignorant and politically misguided public, it is surely the doctor's task to ensure that he does not encourage such widespread abuse of the hospital service. In saying this I am mindful of the fact that daily attempts to "educate" the public, however appealing such an enterprise may seem to politicians and the more starry-eyed of our colleagues, are largely doomed to failure. Nurses and doctors, tiring of the need to argue with patients about their eligibility to attend casualty, often find it simpler to capitulate to public demand.

The problem posed by Mr. Preston and his colleagues does not, in my opinion, argue for the "open door" in casualty, but is surely one of the many cogent and forceful arguments which the profession should advance in demanding root and branch reform of the N.H.S. One hundred per cent. free-at-the time medicine, with its total failure to differentiate the urgent and vital from the more trivial and unimportant, is the chief reason why the N.H.S. is cracking up. Continuation of this type of service, with increasing disenchantment of doctors, must eventually lead to massive breakdown in medical standards.—I am, etc.,

Reginald S. Murley.

London W.1.

Psychological Medicine Group Conference

Sir,—Discussing Section 29 of the Mental Health Act, 1959, Dr. Morris Markowe (10 June, p. 703) claims that the survey of compulsory admissions to 27 psychiatric hospitals conveys a "false impression."

The principal facts (unpalatable to many) reported in the original paper[1] and in a subsequent letter[2] may, however, be conveniently tabulated as follows:

Admissions to Psychiatric Hospitals During 1963

Total	Informal	Sect. 29	Sect. 25	Sect. 26
National Figures				
173,718	138,575 (80%)	22,184 (13%)	8,170 (5%)	2,059 (1%)
Sample of 27 Psychiatric Hospitals				
31,540	24,041 (76%)	4,261 (13·5%)	2,510 (8%)	491 (1·5%)

The psychiatric hospitals in the sample were not specially selected as implied in the report of the Psychological Medicine Group Conference (*Supplement*, 20 May, p. 119); instead two were chosen randomly from each of the 15 regions in England and Wales (three did not complete the questionaries). The sample's representativeness is illustrated by the close approximation of the percentage figures in the national and sample groups. The 1964 national figures are comparable to those of 1963 with respect to Sections 29 and 25,[3] and in these years Section 29 was used more than twice as frequently as Section 25, which is contrary to the letter and spirit of the Mental Health Act.

Is the position all that different now? In 1966, Barton and Haider concluded that "some 5,000 people are now being admitted to psychiatric hospitals in England and Wales annually without adequate scrutiny of the need for compulsion."[4] It will be interesting to observe the impact of the circular letter of 4 October 1966 from the Chief Medical Officer of the Ministry of Health to medical administrators of psychiatric hospitals which emphasized restricting "the use of the powers under Section 29 to the minimum." Dr. Markowe might perhaps care to examine this point for possible inclusion in his forthcoming report.

Unfortunately, it is impossible to reach any general conclusions from analysis of the figures for Shelton Hospital, which has always shown a marked preponderance of Section 25 over Section 29 admissions. In my view this is due to several factors which have been fully elaborated elsewhere,[5] and which if adopted nationally might reduce the proportion of Section 29 admissions to a generally acceptable level.

Meanwhile, in the absence of further conclusive evidence to the contrary, I am inclined to support Dr. Barton's contention[6] that "the present Act is not obsolescent" and that "it is being misused."—I am, etc.,

J. C. Barker.

Shelton Hospital,
Shrewsbury.

Merit Awards in General Practice

Sir,—Surely the time for your closing the correspondence in the *B.M.J.* on this topic is long overdue.

Reading letters on it under different headings week after week gives the impression that you are under pressure from sections of the medical establishment.—I am, etc.,

S. H. F. Howard.

Obituary Notices

D. IOAN-JONES, B.SC., M.B., B.S., F.R.C.S.

Mr. D. Ioan-Jones, emeritus surgeon to the United Cardiff Hospitals, died in Cardiff on 27 June. He was 70.

David Ioan-Jones was born in 1897, and was educated in the University of Wales, graduating B.Sc. in 1919. For his clinical studies he came to London and entered the Westminster Hospital, qualifying with the Conjoint diploma in 1921, and graduating M.B., B.S. three years later. He became house-surgeon and house-physician at the Westminster and surgical registrar to Sir Stanford Cade and the late Mr. Rock Carling. He took the F.R.C.S. in 1929, and in 1932 was appointed assistant surgeon to the Cardiff Royal Infirmary, where he remained until his retirement as senior surgeon in 1963.

As time went on Ioan-Jones won the complete confidence of the profession, and the demands on his services grew almost beyond endurance. Then in 1936 came a sudden break. He had to be admitted to Midhurst Hospital, and while there he had to undergo a thoracoplasty, performed by his old teacher, the late Mr. Tudor Edwards. He made a complete recovery, and was back at work in 1938 at the same intensity until he retired in 1963. For many years he covered a huge mileage, both day and night, especially during the war years, and he always made himself available to serve others.

In 1953 he was vice-president of the section of surgery at the Annual Meeting of the B.M.A., and in 1960 he was appointed for a period of five years as representative of the University of London on the court of governors of the University College of South Wales and Monmouthshire, Cardiff.

As a general surgeon David Ioan-Jones was outstanding, both in his clinical assessment and in his techniques. His rapid gentle movements inside the abdomen were a real pleasure to observe, as was the speed with which he tied his reef knots. He was one of the pioneers in performing adrenalectomy in cases of breast cancer, and the records were carefully kept. Despite his vast surgical experience he could not be persuaded to put pen to paper. One felt that this was a great loss. He used to say that there are too many people doing this. After a hard day's work he preferred to relax with his wife and friends, for he enjoyed good company.

A man of tremendous courage and dignity, he never sought favours by flattery. It is natural to believe in great men. The world is upheld by the veracity of good men ; they make the earth wholesome. David Ioan-Jones was one of these in his own quiet dignified way. "He is great who is what he is from nature." This tranquillity was made possible by the ideal home life that was his blessing.

We extend our deepest sympathy to his wife, Barbara, and his daughter, Mrs. Mathias.—R. D. O.

W. BRIGGS, M.B., B.S., F.R.C.S.

Mr. W. Briggs, a former consultant surgeon to Blackburn Royal Infirmary, died on 2 July. He was 87.

Walter Briggs was born in Blackburn on 15 June 1880. He entered Owen's College, Manchester, in 1897, graduating M.B., Ch.B. in 1902 with second-class honours in the Victoria University, which still included Owens College, University College, Liverpool, and Yorkshire College, Leeds. Two years later he gained the additional qualification of M.B., B.S.Lond. In the meantime he had held resident posts at the Blackburn Royal Infirmary. In 1905 he went to Vienna, then the Mecca of postgraduate education. While there he met, and became engaged to, Miss Florence Taylor, an Australian-born pupil of the great piano teacher Leschetizky. In 1908 Miss Taylor came to Blackburn to become Mrs Walter Briggs, abandoning the idea of a career as a concert pianist for a marriage of great happiness. Their hospitable Blackburn home was always full of the sound of music. In the 1930s my wife and I spent many enjoyable evenings in Blackburn, where I was allowed to play the second piano part to Florence Briggs as soloist in well-known concertos and other works arranged for two pianos.

Walter Briggs started his career in Blackburn as a single-handed general practitioner, but was soon appointed to the honorary staff of the Blackburn Royal Infirmary as assistant surgeon—probably first acting as anaesthetist, as the custom was in those days. The first world war was a turning point in his career. He joined the 64th Casualty Clearing Station as a surgical specialist. The nucleus of this unit was recruited in the Western Command, and for a short time was attached to the 2nd Western General Hospital, Manchester, before going to France in 1917. In 64 C.C.S. Walter Briggs served with distinction with the rank of acting major, being mentioned in dispatches, and there came under the influence of the late Sir Ernest Rock Carling and the great Harvey Cushing, who was working near by at 46 C.C.S. (Mendinghem). In Harvey Cushing's *Surgeon's Journal* there are brief references to these encounters—"To tea with Carling and Briggs" (15 October, 1917). "A full operating day, Briggs and Carling from No. 64 looking on" (Saturday, 20 October 1917). After the war Walter Briggs gradually relinquished general practice, and on the retirement of Mr. R. Y. Aitken became the sole consulting surgeon in the Blackburn area. His wise leadership in the clinical and administrative affairs of the Blackburn hospitals became undisputed. In 1928–9 he was chairman of the Blackburn Division of the Bristol Medical Association, and in 1945 he was elected president of the Manchester Surgical Society, a signal honour for a surgeon from a non-teaching centre. In his earlier years his surgical interests, which were always wide, were for a time focused on orthopaedics. He organized and took charge of the first orthopaedic clinic established in Blackburn with a unit for long-stay patients in the municipal hospital at Queen's Park. During this period he attended regularly the meetings of the British Orthopaedic Association. Later, when the Blackburn Royal Infirmary appointed its first specialist orthopaedic surgeon, Walter Briggs's surgical repertory had become restricted to the procedures of major abdominal surgery and the surgery of malignant disease. His technique in the operating-theatre always showed how deeply he had been influenced by watching Harvey Cushing at work in France. In 1950 Walter Briggs was elected to the Fellowship of the Royal College of Surgeons of England under the "twenty years" rule. This distinction could have come to him much earlier, if by chance he had been an M.R.C.S. A change in the regulations made it possible for the College to recognize him at the age of 70, at the end of his active surgical life.

Walter Briggs was one of the original members of the Manchester Regional Hospital Board, on which he served for seven years, from 1948 to 1955. On his retirement from the affairs of surgery he made several voyages up the Amazon as a ship's surgeon. His devoted wife died in 1954. He is survived by his daughter, Mrs. Arthur Carter, of Darwen, five grandchildren, and four great-grandchildren.—H. P.

J. R. writes: As a general practitioner closely associated with Mr. Briggs for 33 years, I would add my appreciation of a man who was not only a close personal friend but also a very esteemed colleague. Mr. Briggs was that rare person who had great integrity, professional honesty, absolute devotion to medicine and surgery (for he was a general practitioner before he became a consultant in surgery), and an appreciation of the realities of life. He loved the fine things of life : flowers, good music, good literature, a beautiful day, and, above all, the Lake District, which he knew intimately. He was also a sportsman, both actively as a young man and later as a spectator.

Mr. Briggs's professional ability was great as a diagnostician and as a surgeon. To have him to see a case in a consultative capacity was a great experience both for the patient and for the general practitioner concerned. His skill in diagnosis and his understanding of the human problems involved were a pleasure to doctor and patient alike. For many years he was honorary consulting surgeon to Blackburn Royal Infirmary, where his name is held in great respect and awe, and where a ward is named after him. With the advent of the National Health Service in 1948 he stayed on as a consulting surgeon for two more years, until he was 70. He was a member of the hospital management committee and one of the first members of the newly formed North-west Regional Hospital Board, where his great gifts of knowledge and personal charm helped to launch this enterprise.

Mr. Briggs had lived with his daughter since the death of his wife, and looked after quite a large garden until August 1966, when his health began to fail. He bore his last illness with great fortitude and bravery, and with the spirit which had guided him all through his long life. To have known him so intimately was a great and rare privilege.

Brigadier R. V. FRANKLIN, O.B.E.
M.B., B.CH., B.A.O., A.M.S.(RET.)

Brigadier R. V. Franklin, a former inspector of training, Army Medical Services, died suddenly on board his yacht on 2 July. He was 64.

Robert Vincent Franklin, son of Lieutenant-Colonel R. J. Franklin, R.A.M.C., was born at Aldershot on 27 January 1903, and was educated at the University of Dublin, graduating M.B., B.Ch., B.A.O. in 1925. He went to sea for a short time as ship's surgeon before joining the R.A.M.C. in 1926 and specializing in otology. He was sent to India in 1927, where he served until he was sent to Burma and the Far East during the second world war. He was mentioned in dispatches, and in 1945 was appointed O.B.E. After serving in Germany and Egypt he returned to Britain for a period of four years as assistant director of medical services in Scotland and northern England before going out to Singapore in 1952. In 1953–4 he served in Korea as deputy director of medical services and then returned to Britain as inspector of training, Army Medical Services, from 1955 to 1960, when he retired from the Army and again took up a position as ship's surgeon.

R. M. H. writes: Bob Franklin first went to sea in 1926 because of his tremendous love of it, which never forsook him, and it was fitting that his passing should have occurred while yachting. After a life afloat he joined the R.A.M.C. and became an E.N.T. specialist, at which he was extremely gifted. With promotion came more administrative responsibility. His close co-operation with the Royal Naval medical services gave him infinite pleasure.

On his retirement from the Army with the rank of brigadier he joined Cunard, and served as surgeon and principal medical officer in their *Parthia, Media, Sylvania, Carinthia, Mauretania, Queen Mary,* and *Queen Elizabeth.* He was a strict disciplinarian, and his departments ran well. Clinically he was sound, and even after many years with administrative work he could still perform general surgery admirably. His zest for the social life made him an incomparable shipmate, and his table from the passengers' angle was always sought after for its wonderful conviviality. There is no doubt about it that those who go to sea possess a quality of human understanding that other spheres miss, and Bob Franklin possessed this in wide measure.

H. L. GULATI, M.R.C.S., L.R.C.P.
D.O.M.S.

Dr. H. L. Gulati, a general practitioner and ophthalmologist and former London County Councillor, died suddenly on 13 June. He was 70.

Harbans Lall Gulati was born in the Punjab in 1896 and received his medical education at Lahore. In 1916 he became an officer in the Indian Medical Service and saw service on the North-west Frontier. In 1920 he worked his passage to England. His medical degrees were not recognized here, and he had not only to take his matriculation and qualifying exams again but had once more to go completely through medical school. Entering Charing Cross Hospital Medical School, he qualified with the Conjoint diploma in 1926. Almost at once he took up general practice in Battersea and remained in active practice there for over 40 years up to the time of his death.

Dr. Gulati entered politics in 1934 and became a Conservative member of the borough council, serving on committees concerned with health, libraries, national savings, and a variety of other subjects. In 1940 he became a magistrate and served regularly on the South-western Petty Sessional Division thereafter. During the second world war his social work, particularly for children and old people, is well remembered. He was active in pioneering the "meals-on-wheels" service, and in the St. John and Red Cross organizations. In 1945 he took the D.O.M.S., and soon afterwards began his association with the Royal Westminster Ophthalmic Hospital.

In 1947 Dr. Gulati resigned from the Conservative party over their antagonistic attitude to the National Health Service. Shortly afterwards he joined the Socialist Medical Association, and became its secretary. Joining the Labour party, he soon found himself on the borough council once more. In 1955 he fought the London County Council elections, and was returned as a member for South Battersea. Later he became prospective Parliamentary candidate, but pressure of work made him give up active politics and he never achieved his ambition of getting into Parliament.

Lall, as he was known to practically everyone, was a great man. He faced problems squarely, and overcame them with a combination of strength, industry, and tact. The shortest encounter with him left a lasting impression. He was held in awe by many and in great esteem by his patients, many of whom travelled great distances to see him after leaving the district. He was a fighter and had a remarkable zest for life, and loved good food and good company. He seldom spoke of his early days in England, when he arrived penniless and without friends or relatives. He did unskilled work, often at night, to put himself through medical school, and he vowed others would not have to suffer similar adversity. For this reason he later became an active member of the management committee of the Indian Y.M.C.A. and saw this institution completely replanned and rebuilt. He was also a Freemason. Recently he had returned from Japan and had produced a paper on the legal system of that country, and at the time of his death he was writing his autobiography.

He is survived by his widow, two sons, one of whom is in the medical profession, and one daughter.—R. L. G.

Colonel P. J. RYAN, M.C., M.A., M.SC.
M.B., B.CH., B.A.O., A.M.S.(RET.)

Colonel P. J. Ryan, formerly of the Army Medical Service, died peacefully at Rye Hospital on 29 June—his eightieth birthday—after a distinguished medical career in the Army.

Peter John Ryan was born in Ireland on 29 June 1887, and received his medical education at the University of Dublin, graduating M.B., B.Ch., B.A.O. in 1911. A keen sportsman, he enjoyed hunting, fishing, polo, yachting, and skiing, and won many trophies at golf. A rugger player, he captained Lansdowne Rugby Club in Dublin. In his leisure moments he was a keen bridge player, winning an international trophy. He was one of the last batch of regular Army officers who joined the R.A.M.C. in 1914 by free competition, but before doing so he had travelled round the world twice as a ship's doctor and had learned much about men. He served in the first world war and was awarded the M.C. in 1918 and mentioned in dispatches. He was also thrice awarded the Croix de Guerre. He served during the 1936–7 campaign against the Fakir of Ipi on the North-west Frontier of India, and between the two world wars saw active service in Egypt, Mesopotamia (Iraq), and India, again being mentioned in dispatches. He commanded "A" company at the R.A.M.C. depot for several years. In the second world war he served as A.D.M.S. of North Wales district of Western Command, where I first met him at Shrewsbury headquarters, and served under him for three years.

Peter Ryan as an officer and doctor and in his whole life was a man of the highest moral, ethical, and Christian standards, and in his Army work and administration he lived up to them to the hilt. He was energetic and conscientious in everything he did and ordered to be done, giving and demanding efficiency in every detail by himself and those under him alike. He was one of those men of whom one can truthfully say one was glad to have known and worked with him. In retirement he was full of energy and efficiency in his beautiful home and garden at Icklesham in Sussex. He had become very interested in horticulture, winning many awards at local shows. His continued enthusiasm for efficient activity found outlets by his participation in village life and affairs. He was a member of Icklesham parish council, chairman of several local charities, including the Icklesham almshouses—the modernization of which was almost entirely due to his tireless negotiation and hard work. For many years he was chairman of Queen Mary's Home for Retired Army Nurses, and president of Pett and District British Legion. He was also the honorary treasurer of Area I Sussex Home Physiotherapy Service, into the inauguration of which service, and to the running of it afterwards, both he and his wife poured much energy. He also organized the covenant scheme for St. Anthony's Roman Catholic Church in Rye.

It is good that he lived to such a grand old age to enjoy useful work after his professional retirement, but his loss is still a very great one, and our sympathy goes out to his widow, two daughters, and five grandchildren, all of whom loved him dearly and will greatly miss him.—R. M. P.

C. J. LEWIS, M.D., M.R.C.P., D.P.H.

Dr. C. J. Lewis, a general practitioner at Walsall, died on 20 June. He was 69.

Charles John Lewis was born in Birmingham on 28 April 1898, and was educated at King Edward's School and Birmingham University, graduating M.B., Ch.B. with honours in 1921, and taking the Conjoint diploma the same year. After house appointments at Birmingham General Hospital and the Queen's Hospital for Children in London he proceeded M.D. in 1922 and took the M.R.C.P. two years later. He went into general practice at Cradley Heath, Staffordshire, in 1927, and in 1934 took the D.P.H. He came to Walsall in 1932, where he worked hard in a large industrial practice, combining this with the posts of medical officer to the G.P.O. and as one of the town's parish poor-law doctors. He also at one time held the posts of anaesthetist to Burntwood Military Hospital, and clinical assistant at Birmingham Skin Hospital.

Dr. Lewis put in a lifetime of hard and devoted work in the Midlands up to the onset of his illness in February of this year. He was due to retire at the end of June, and was planning many projects to be fulfilled during his retirement. He was a keen member of the B.M.A., always taking an active and enthusiastic part in Divisional meetings. His hobbies included gardening—orchids and carnations being his principal interest—and china, particularly that of Staffordshire, Chelsea, and Nantgarw. He is survived by his wife and two adopted daughters, to whom we extend our deepest sympathy.—W. B. McC.

J. STIRLING, M.A., M.D.

Dr. J. Stirling, formerly in general practice at Aldridge, Staffordshire, died in Walsall General Hospital on 3 June at the age of 73.

John Stirling was born in Alexandria, Dunbartonshire, in 1893, and received his education at the Vale of Leven Academy. As a young man he ran a boys' club at Bonhill North United Free Church, and from this stemmed his deep interest in the welfare of young persons, which continued throughout his life. After a short period as a schoolmaster he enlisted in the R.A.M.C., from which he was discharged after a serious accident which left him with a permanent disability. He never complained, and never allowed the disability to interfere with his activities. It was after his Army service that he decided to study medicine, and he entered Glasgow University, where he graduated M.B., Ch.B. in 1920, and M.A. in the same year. He proceeded M.D. in 1931. He settled in general practice in 1921 in Aldridge, where he remained for the whole of his professional life. He was the perfect general practitioner, devoted to his patients and beloved by them all.

Dr. Stirling had a wide range of interests, and for many years he was a very active member of Walsall Hospital Management Committee. He was a magistrate and took a particular interest in the juvenile court. For some years he was medical officer at Druids' Heath Approved School, and then chairman of the managers, and was an accepted authority on the problems of juvenile delinquency and the work of approved schools. He was a founder member and past president of Aldridge Rotary Club, one of the founders, and for many years chairman, of the Aldridge Community Association, and an enthusiastic exponent of Scottish dancing. In 1925–6 he was president of the Walsall Burns Club. He was a divisional surgeon in the St. John Ambulance Brigade for upwards of 40 years, and throughout the second world war he was medical officer in charge of Aldridge First Aid Post. From 1938 to 1941 he was chairman of the Walsall and Lichfield Division of the British Medical Association. A keen gardener, he was never happier than when sharing his plants and flowers with his friends, so many of whom have treasured memories in the form of plants which started their lives in his lovely garden. Throughout his life he was a sincere and devoted member of the Presbyterian Church, and for a great many years he was Session Clerk of Walsall Presbyterian Church. His two outstanding qualities were friendship and leadership: his friendship was loyal, lasting, and completely unselfish, and his leadership was by personality, example, persuasion, and explanation, but never by dictation.

To his widow and to his two sons (one of whom was in general practice with him) his many friends and associates extend deep and sincere sympathy.—F. L. R.

T. E. JAMES, M.R.C.S., L.R.C.P.

Dr. T. E. James, a general practitioner of Clydach Vale, Rhondda, died at his home on 1 June after a long illness. He was 65.

Thomas Ellis James was born in Clydach Vale on 14 April 1902, and received his medical education at the Welsh National School of Medicine, Cardiff, qualifying with the Conjoint diploma in 1927. He spent a short time as an assistant at Cilfynydd, Pontypridd, before returning to Clydach Vale to build up his own practice single-handed. He worked exceedingly hard, and by the start of the National Health Service had succeeded in creating a large practice spreading well beyond Clydach Vale into neighbouring districts. In 1953 he entered into partnership and continued his work in the practice where he knew his patients so well. One of his greatest assets was an encyclopaedic memory for all his patients and their interrelationships, and this enabled him to be a real family doctor and to help his patients in so many ways other than in purely medical matters.

Dr. James was active outside his practice, and was chairman of the North Glamorgan and Brecknock Division of the British Medical Association in 1961–2, a past-president of the Rhondda Medical Society, a past chairman of the Rhondda Rotary Club, and also served on many local committees. He was a serving officer of long standing of the St. John Ambulance Brigade. A superb raconteur and after-dinner speaker, he will be remembered by many.

All his patients—and many who were not patients—held Dr. James in great esteem. He was kind to everyone and always ready to help. On his retirement on 31 March of this year his patients and friends showed their appreciation by presenting him with a substantial testimonial. Although he was aware of the inevitable outcome of his long illness, he bore it with great courage and without complaint.

All extend their deepest sympathy to his widow and their family.—D. C. S.

A. H. FERGUSON, B.A., B.M., B.CH.

Dr. A. H. Ferguson, a general practitioner in Lincoln, died suddenly on 27 June. He was 49.

Alan Hudspeth Ferguson was born at Anfield Plain, County Durham, on 22 June 1918, and was educated at Newcastle Grammar School and Nottingham High School, gaining a scholarship at Wadham College, Oxford, where he obtained first-class honours in physiology before proceeding to clinical studies at the London Hospital. He graduated B.M., B.Ch. in 1942. After an appointment as house-physician at the Norfolk and Norwich Hospital he served during the second world war as captain in the R.A.M.C. After demobilization in 1946 he entered general practice in Lincoln.

Alan Ferguson ("Fergi") gave a quite exceptional quality of medical care to his patients. His work was his answer to the critics of family practice, especially to those who complain of diminishing public confidence in general practitioners. This was due in large measure to the time he was prepared to devote to them and the energy he put into his own continued medical studies. These and a degree of self-discipline obvious to all who knew him enabled him to develop a particularly personal type of family practice rarely found in these days, especially in urban districts. Such an approach naturally made him sought after as a general-practitioner obstetrician, an aspect of work which he enjoyed. His competence and knowledge of his patients enabled him to accept justifiably much responsibility, thus sparing many of them unnecessary investigation and treatment. His work left little time for committees, but for many years he was a member of Lincoln No. 2 Hospital Management Committee.

Those who came to knew Fergi well were, at first, surprised by his wide range of reading, and were glad when in recent years he took up photography to add a special interest to his brief travels in Europe, often motivated by his interest in history. His sudden death will be a great loss to Lincoln, and his many patients, colleagues, and friends will miss his guidance and dedication. We extend our deepest sympathy to his wife and his two sons, one of whom is studying medicine.—E. P. M.

News and Notes

EPIDEMIOLOGY

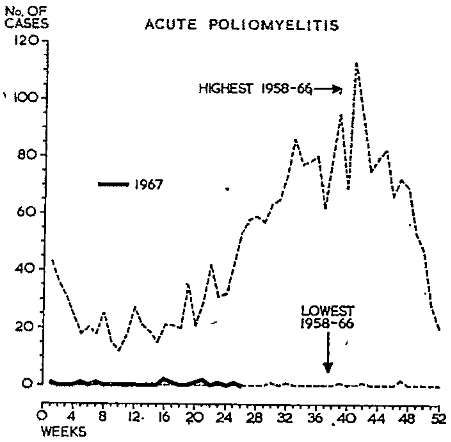
Eire in First Quarter

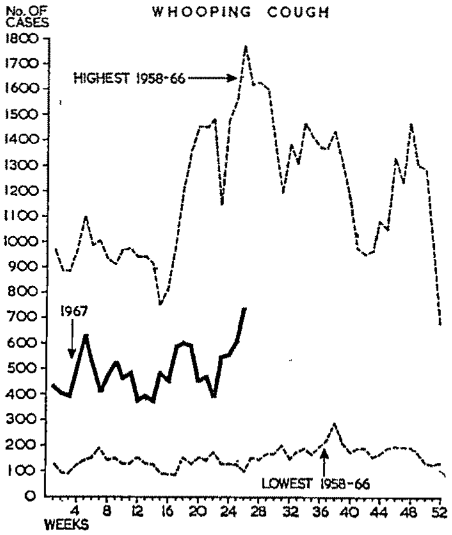
The birth rate in Eire during the first quarter of 1967 was 20.5 per 1,000 population, being 0.5 below the rate for the preceding first quarter. The infant mortality rate was 25 and the neonatal mortality rate was 15 per 1,000 registered births, and these rates were 2 and 3, respectively, below the rates for the first quarter of 1966. The death rate was 11.2 per 1,000 population, being the lowest rate for any recent first quarter.

Deaths from the principal infectious diseases included 43 from influenza, 33 from gastroenteritis under 2 years, 2 from measles, and 1 from whooping-cough. Deaths attributed to cancer numbered 1,230, and of these 512 were due to malignant neoplasm of the digestive system and 222 to malignant disease of the respiratory system. There were 1,447 deaths from coronary and arteriosclerotic heart disease and 741 from other myocardial degeneration.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of acute poliomyelitis and whooping-cough in England and Wales. Figures for 1967 are compared with the highest and lowest figures for each week in the previous years shown.





INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending **1 July** (No. 26) and corresponding week 1966.

Figures of *cases* are for the countries shown and for Greater London. Figures of *deaths* and *births* are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

PARLIAMENT

Abortion Bill Through the Commons

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Almost a year after its second reading, on 22 July 1966, the Medical Termination of Pregnancy Bill has finished the course in the House of Commons. It went through by a majority of about two to one—roughly that which had sustained it throughout two all-night sittings—just before noon on Friday, 14 July. The final vote was: for 167, against 83.

The Bill now faces equally stiff opposition in the House of Lords. By the time this is read the second reading stage there will be over, and prelates, politicians, and practitioners in the peerage will have declared their intentions towards it.

Conscience Clause

In this connexion, the most significant event in the final 14-hour marathon in the Commons was the indication given by the sponsor, Mr. DAVID STEEL, Liberal M.P. for Roxburgh, Selkirk, and Peebles, that the conscience clause (Clause 4) was bound to be reconsidered in the Lords.

The last amendment discussed was a proposal to delete from the clause the provision that in any civil or criminal action the burden of proof of conscientious objection should rest on the person claiming it. The amendment was put forward on the ground that the clause departed from the principle that the burden of proof should rest with the person making the charge.

Mr. STEEL, opposing the change, said the Royal College of Obstetricians and Gynaecologists and the British Medical Association had now come forward with certain views, but there had not been time to take all the advice necessary and to consider the implications of their suggestions. They had accepted, in their correspondence with him, that this would probably have to be dealt with in the House of Lords.

The Minister of Health had said it was the view of a substantial body of the profession that the clause was unnecessary and raised unnecessary complications. He (Mr. Steel) thought they should continue to try to secure a clause that would satisfy those who believed there should be some clear conscience clause in the Bill. But in providing a conscience clause they must be careful not to leave a loophole for an open defence that could not be substantiated.

He recognized the concern that had been expressed about the wording of the clause, and was not closing his mind to representations. All the views put forward would be carefully considered by him and the leaders of the medical profession when they considered what amendments should be made to the Bill in its passage through the Lords.

After hearing the Government view that it was desirable to have this safeguard, and that the proviso should be retained, the House rejected the amendment by 139 votes to 70, and eventually gave it a third reading and dispatched it to the other House.

Care of the Elderly

The Minister of Health, Mr. KENNETH ROBINSON, who has consistently answered the anonymous charge of maltreatment in the Health Service with a demand for names and places, has now been given the names of the hospitals concerned in the book *Sans Everything* and has asked for sufficient detail to facilitate independent inquiry. He has also accepted that there is a fear of reprisals among nursing staff if they make complaints and is discussing with the Royal College of Nursing how to dispel it.

These consequences of the publicity which the book attracted were made known to the House of Commons in a debate on the care of the elderly on 11 July. Mr. Robinson said he had now asked for sufficient particulars to relate each hospital to a specific section of the book, so that hospital board chairmen could arrange for inquiries to be carried out by a legally qualified chairman from outside the National Health Service, assisted by other persons unconnected with the hospital concerned. More generally, managers of all hospitals have been asked to make searching inquiries into the possibility that any form of inhumanity, particularly in the treatment of elderly patients, might exist in any of the hospitals for which they were responsible.

Mr. Robinson emphasized that no one at this stage could say with certainty that any of the allegations were true or untrue. Should it prove that even a single charge of brutality or inhumanity was substantiated he welcomed its exposure. But the other side of the balance sheet should not be overlooked. The method of presentation—a series of anonymous charges against unidentifiable persons in unnamed hospitals—had caused unmeasurable distress and anxiety not only to nursing and other staff but to relatives and friends of patients, present and future.

Complaints from Nurses

On the suggestions that nursing staff and others were afraid to come forward with complaints for fear of reprisals, he said his first reaction had been to dismiss this possibility out of hand. He had since seen the questionary published in the *Nursing Mirror* of 16 June, and a selection of replies. These had convinced him that such fears did exist, at least among a small minority, and he was considering what might be done to dispel them. Senior officers of the Ministry had discussed this with the President of the Royal College of Nursing, and they would be considering what further action would be appropriate.

"I have no evidence," he summed up, "that any patients are deliberately ill-treated, as alleged in *Sans Everything*. I am ready and anxious to investigate anything which can be investigated. I am determined that if there are malpractices in any hospital they shall be uncovered and eliminated." And he promised that nurses who came forward would be given all the protection that he could.

Hospital Commission?

Miss MERVYN PIKE, Opposition leader on social topics, endorsed the views of Professor ABEL-SMITH that there should be a hospital commission responsible for investigating complaints, and an inspectorate similar to that in the education service, which could be equally valuable in health and welfare. There should be more spending on hospitals. The shortage of beds and pressure on resources was aggravated because too many old people had to be kept in hospitals and mental homes because they had nowhere else to go. Many more homes were needed for old people. In far too many places there were long waiting-lists, inadequate and unsuitable buildings, and untrained and overworked staff. A recent article in the *British Medical Journal* had argued that a unified health service should be fitted in with any reformed local government structure. Much could be done also to prevent overlapping in the local authority services. It was a delusion that the inevitably escalating demands of the future could be met by relying on steeply rising taxation to pay the social welfare bill. In face of the present difficulties the B.M.A. had decided to plan an alternative health service. Parliament should realize that the time had come to take a good hard look at the alternatives to the present system.

Geriatric Services

Mr. ROBINSON, recalling his request on regional hospital boards in 1965 to give geriatric and psychiatric services "a due and early share" of resources available, said there was already some evidence of progress. In 1966 there were 59,186 geriatric and chronic sick beds. The regional boards estimated that in 1970 there would be 63,048, an increase of 7%, which would keep pace with the rise expected in the elderly population.

There had also been a considerable strengthening of medical staffing: the number of consultants specializing in geriatrics had risen by nearly 40%—from 115 in 1964 to 156 in 1966. The challenge of this specialty was being more widely appreciated, and this should be helped by a new development among teaching hospitals. Most of the London undergraduate teaching hospitals had recently undertaken, or proposed, to provide full hospital services to their local communities, including geriatric patients. This would mean that geriatric care would benefit from the stimulus of a large teaching hospital. He was glad to note that the Royal College of Physicians had recently recognized the value of the specialty by setting up a geriatric committee.

Money the Core

Dr. M. P. WINSTANLEY (Cheadle, Lib.) said a crucial point in the whole problem of the care of the elderly was the existing situation of divided responsibility. There was a "fairly urgent need for the appointment of an old persons' officer whose sole duty would be to make himself or herself aware of the size of the problem in the area, identify the people, and ensure that the various sources of assistance and health were integrated." They must speed up the end of the tripartite system within the Health Service. If they persisted in having these organizational divisions, they would never get the kind of integration they wanted. He concluded by saying that all discussions came down to one thing in the end: money. Unless more money was spent on the provision of resources for the care of the elderly, no amount of talking would do any good.

Dr. SHIRLEY SUMMERSKILL (Halifax, Lab.) declared that the money should come entirely out of the national income and that more of the national income should be spent on health.

Dr. DAVID KERR (Wandsworth, Central, Lab.) disagreed with the idea of a hospital commissioner. The value of the book they had been discussing lay in the message implicit throughout that the whole hospital system should be thrown open to public gaze. Such occurrences as the book described would then not occur.

MEDICAL NEWS

Appointments to Personal Chairs

Dr. E. J. FIELD has been appointed to a chair in experimental neuropathology, personal to himself, at the University of Newcastle upon Tyne.

Dr. Field, who is 52, graduated M.B., B.S. from the University of Durham in 1938. After holding house appointments he became the surgical registrar and demonstrator in anatomy at Newcastle and later senior demonstrator and lecturer in anatomy at St. Bartholomew's Hospital Medical College. He proceeded to the M.S. in 1944 and the M.D. in 1946, and in the same year he was appointed lecturer in anatomy at Bristol University. After working at the Institut Pasteur, Paris, and in the University of Geneva he took the Ph.D. (Bristol) in 1953. He returned to Newcastle in 1958 as senior lecturer in neuropathology, and in 1961 he was appointed honorary director of a newly established Medical Research Council Group on Demyelinating Diseases. This group was converted into a Medical Research Council unit in 1965, Dr. Field continuing as the honorary director. His research on immunology and autoimmune disease has dealt especially with multiple sclerosis and experimental allergic encephalomyelitis. Transmission studies with multiple sclerosis material both in vivo and in tissue culture have recently led to an interest in "slow" virus diseases.

Dr. D. S. MUNRO has been appointed to a personal chair of clinical endocrinology in the department of pharmacology and therapeutics at Sheffield University. Dr. Munro, who is 42, graduated at Aberdeen University in 1947, and after appointments as house-physician at Aberdeen Royal Infirmary and as assistant in the department of materia medica in the university became M.R.C.P. in 1949. On demobilization from the R.A.M.C., in which he served as a junior medical specialist in the Far East, he was registrar in medicine to the Aberdeen teaching hospitals, and in 1953 he was appointed lecturer in therapeutics at Sheffield University. From 1957 to 1958 he was Research Fellow in Endocrinology with Dr. E. B. ASTWOOD at the New England Medical Centre, Boston, Massachusetts. On returning to Sheffield he was promoted senior lecturer in 1959 and became reader in clinical endocrinology in 1965. He was elected F.R.C.P. this year. His M.D. thesis on clinical applications of isotope dilution techniques was accepted in 1956. He has also published papers on electrolyte metabolism in Addison's disease and on applications of the use of radioactive isotopes in the study of body composition. Recent research interests have been in the bioassay of thyroid stimulating substances and on the nature and significance of the long-acting thyroid stimulator of hyperthyroidism.

Clinical Biochemistry Chair

Dr. H. LEHMANN, University biochemist to the Cambridge United Hospitals, has been pre-elected professor of clinical biochemistry from 1 October. Dr. Lehmann was educated in Dresden and studied medicine at the Universities of Freiburg, Frankfurt, Berlin, and Heidelberg, obtaining awards for anatomy at Frankfurt and for gynaecology at Berlin. (In 1964 he delivered the Ludwig Aschoff lecture at Freiburg and was made an honorary professor of that university.) Because of the political atmosphere in 1933 in Germany he went to Basle for his M.D., and then returned to Heidelberg to work under Professor OTTO MEYERHOF. From Heidelberg he went to Cambridge and became a research student at Christ's College. In 1938 he obtained the Ph.D., was awarded the Darwin Prize of Christ's College, and was elected a Beit Memorial Fellow.

Shortly after the outbreak of the war he worked as a medical officer, first in Essex, and then for several years in the R.A.M.C., mostly in India Command. After the war he went to Uganda for two years to work at Makerere College on hookworm anaemia. On his return he spent a year as a consultant pathologist at Pembury Hospital in Kent and then joined St. Batholomew's Hospital, where he remained for 13 years. He continued to make contributions in the field of abnormal haemoglobins, and in 1962 the Medical Research Council set up a unit concerned with this subject, and made him honorary director. This unit, now at the Cambridge University department of biochemistry, has recently been made the World Health Organization Centre on Abnormal Haemoglobins. In 1963 Dr. Lehmann rejoined the biochemistry department at Cambridge as its University biochemist to Addenbrooke's Hospital, and was made a Fellow of Christ's College.

Kidney Centre to Close

The National Kidney Centre at Finchley, N. London, has decided not to take on any new patients and will close within a year. Responsibility for 27 patients already receiving treatment has been assumed by the Ministry of Health. The centre was set up last November as a private concern to treat patients by dialysis in their own homes. In a statement on 13 July the Ministry reported that a deputation from the centre "indicated that they now accept the Ministry's view that the centre is not viable without the full medical resources of a hospital." Dr. Stanley Shaldon, the medical director, proposes to relinquish his post by 1 July 1968. (A letter from Dr. Shaldon appears at p. 241.)

Medical Research Council

Professor A. W. Kay, Regius Professor of Surgery at Glasgow University, and Professor R. A. Gregory, F.R.S., George Holt Professor of Physiology at Liverpool University, have been appointed members of the Medical Research Council. They succeed Professor Sir Hedley Atkins, P.R.C.S., and Professor W. D. M. Paton, F.R.S., who retire in September on completing their terms of office.

Opening of Medical Centre

The new postgraduate medical centre at Good Hope General Hospital, Sutton Coldfield, which Professor Sir Max Rosenheim opened on 15 July, has been completed at a cost of £27,000. The greater part of this sum was donated by a local benefactor, but the Birmingham Regional Hospital Board also made a substantial contribution (see *B.M.J.*, 9 July 1966, p. 123). Facilities include a fully equipped lecture theatre, with accommodation for just over 100, a library, seminar-room, and a common-room, as well as the usual administration offices. The centre will be used by the hospital senior medical staff for interdepartmental rounds and teaching sessions. Courses, in addition to regular lectures and demonstrations, are expected to be held for general practitioners. It is hoped that the centre will be integrated with others in the Birmingham area, so that courses for higher degrees can be run in conjunction with other hospitals.

Central Health Services Council

Subjects discussed in the report for 1966 of the Central Health Services Council (H.M.S.O., 3s. net) include the visiting of children in hospitals, expansion of screening for cervical cancer, and the need for psychiatric beds in teaching hospitals. During the year the Council set up a new committee to consider the functions of the district general hospital. A new subcommittee on acute poisoning was also set up. In a statement introducing the report the Minister of Health, Mr. Kenneth Robinson, acknowledges the help given by the council throughout the year.

British Empire Cancer Campaign

The annual general meeting of the British Empire Cancer Campaign for Research was held on 4 July in the Assembly Hall of the Royal Commonwealth Society, the Duke of Devonshire presiding. Some 200 members of fund-raising committees in all parts of the country attended. The Nuffield Trophy, awarded for the best fund-raising efforts made during the year, was presented to Lord Rowallan on behalf of the Glasgow committee. Professor T. Crawford, director of the department of pathology, St. George's Hospital Medical School, has succeeded Professor R. W. Scarff as honorary secretary, and Viscount Mills has succeeded Sir Joseph Lockwood as honorary treasurer.

"Medical Directory"

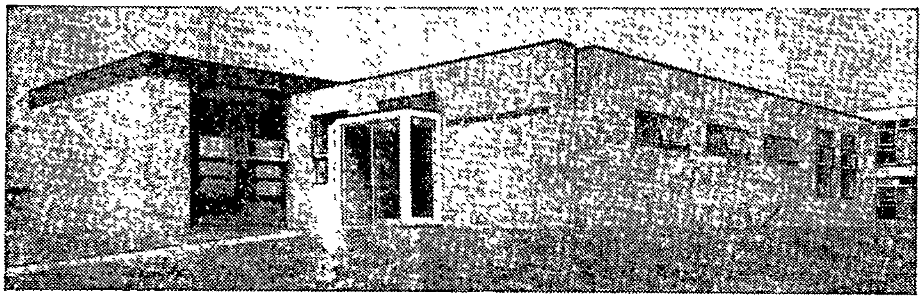
The posting of the annual schedule for the *Medical Directory*, 1968, has been completed. It is desired to include the names of all fully and provisionally registered medical practitioners living or working in the British Isles, and also the names of British-qualified doctors living or working abroad. All such practitioners who have not received the schedule are asked to communicate at once with the Editor, *Medical Directory*, 104 Gloucester Place, London W.1, stating full name and year of qualification.

People in the News

Dr. Geoffrey Templeman, Vice-Chancellor of Kent University, has been re-elected Chairman of the Universities Central Council on Admissions for the period 1 August 1967 to 31 July 1970.

Grants and Awards

The Ministry of Health has made a grant of £3,454 to enable Professor M. Roth, of the University of Newcastle upon Tyne, to undertake an investigation entitled "Psychometric Screening of the Aged in the Community."



Medical Centre at Good Hope General Hospital, Warwickshire.

News in Brief

The Worshipful Company of Barbers of London is appealing for £300,000 to rebuild the Barber-Surgeons' Hall in Monkwell Square, London Wall. Cheques should be sent to Mr. John H. L. Trustram, 31 Bedford Street, London W.C.2.

Members of Regent House at Cambridge University decided last week by 244 votes to 213 that they would not raise overseas students' fees. Oxford University has also rejected the Government's decision.

The World Health Organization supported 1,276 projects in 1966 in 152 countries and territories.

Recent Publications

The *Compendium of University Entrance Requirements* for first degree courses in the United Kingdom in 1968–9 has been published by the Association of Commonwealth Universities. Copies can be obtained from Percy Lund, Humphries & Co., Ltd., The Country Press, Priestman Street, Bradford 8, price 14s. 6d. (post free in the United Kingdom). The compendium does not supersede the official publications of individual universities.

Coming Events

British Occupational Hygiene Society.—Conference on health hazards in docks and shipyards, 12–13 September, University of Newcastle upon Tyne. Details from honorary scientific secretary, Mr. D. C. Murphy, Medical Department, Esso Refinery, Fawley, Southampton.

Institute of Diseases of the Chest.—Course in respiratory diseases for medical senior registrars and registrars, 18–22 September. Fee £7. Applications to Mr. R. A. Perkins, Institute of Diseases of the Chest, Brompton Hospital, London S.W.3.

British Association for Social Psychiatry.—Seminar, 24–30 September, Queen's College, Oxford. Details from Conference Secretary, 62 Great Cumberland Place, London W.1.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Monday, 24 July

Institute of Laryngology and Otology.—5.30 p.m., combined staff consultation clinical meeting.

Tuesday, 25 July

Royal Postgraduate Medical School.—4 p.m., Mr. G. C. Knight : Whiplash Injuries and Cervical Spondylosis.

West Suffolk Hospitals Postgraduate Centre.—At Outpatient Hall, West Suffolk Hospital, 8.15 p.m., clinical meeting.

Wednesday, 26 July

B.B.C.—1 Television.—11.15 p.m., medicine today: Heart Failure. (Sponsored by A.S.M.E.)

Stoke Mandeville Hospital.—12.15 p.m., Sir Max Rosenheim: Investigation of Hypertension in a Young Adult.

Friday, 28 July

Royal College of Physicians of Edinburgh.—5 p.m., Mr. N. G. C. Hendry: Medicine and the European Economic Community.

Royal College of Surgeons of England.—5 p.m., Victor Bonney lecture by Mr. S. Way: Gynaecological Oncology before and after Victor Bonney.

Royal Postgraduate Medical School.—10.15 a.m., Research in Progress.

Saturday, 22 July

Cambridge University Medical School.—At Chesterton Hospital, 10.30 a.m., all-day symposium: Urological Problems in the Elderly.●

Appointments

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—P. Kellett, M.R.C.S., M.A.N.Z.C.P., D.P.M. (consultant psychiatrist, St Audry's Hospital, Melton); P. S. Dhasmana, M.B., F.R.C.S., D.L.O. (consultant E.N.T. surgeon, Norwich, Lowestoft, and Great Yarmouth Hospital group).

EASTERN REGIONAL HOSPITAL BOARD.—K. M. Parry, M.B., D.C.H. (senior administrative medical officer, Eastern Regional Hospital Board in Dundee).

FRENCH HOSPITAL AND DISPENSARY.—G. H. Jantet, M.B., F.R.C.S. (honorary consultant surgeon).

MANCHESTER REGIONAL HOSPITAL BOARD.—J. M. Abraham, M.B., M.R.C.P., D.C.H. (whole-time or maximum part-time consultant paediatrician, Oldham and District, and Ashton, Hyde and Glossop groups of hospitals); M. Ata, M.B., M.R.C.P.Ed., M.C.Path. (whole-time or maximum part-time consultant pathologist (with special experience in haematology), Rochdale and District group of hospitals); D. A Pitkeathly, M.B., M.R.C.P.Ed. (whole-time or maximum part-time consultant rheumatologist, in regional board hospitals and the United Manchester Hospitals); G. G. Hay, M.B., D.P.M., D.C.H. (whole-time or maximum part-time consultant psychiatrist, Bolton and District group of hospitals); E. A. Allcock, M.B., F.R.C.S., F.R.A.C.S. (whole-time or maximum part-time consultant surgeon, South Cheshire group of hospitals); J. H. Green, M.B., M.Ch.Orth., F.R.C.S.Ed. (whole-time or maximum part-time consultant traumatic and orthopaedic surgeon, Salford group of hospitals); Shiela G. Maddock, M.B. (whole-time consultant physician in geriatrics, Salford group of hospitals).

MINISTRY OF OVERSEAS DEVELOPMENT.—G. R. Randall, M.B., B.S. (medical and health officer, South Pacific Health Service).

MORGAN-HUGHES, J. A., M.D., M.R.C.P. (consultant neurologist, National Hospitals for Nervous Diseases and North-west Metropolitan Regional Hospital Board).

NATIONAL HOSPITALS FOR NERVOUS DISEASES.—H. Merskey, D.M., D.P.M. (consultant physician in psychological medicine).

NORTH-EAST METROPOLITAN REGIONAL HOSPITAL BOARD.—Suzanne L. Alexander, M.B., B.S. (consultant dermatologist, Ilford and District group).

NORTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—R. P. Britt, M.B., M.C.Path. (consultant pathologist, Hillingdon Hospital); D. C. Adamson, M.R.C.S., F.F.A. R.C.S. (consultant anaesthetist, Luton and Dunstable and Associated Hospitals); Audrey A. Boutwood, M.B., M.R.C.O.G. (consultant obstetrician and gynaecologist, Elizabeth Garrett Anderson Hospital); L. N. Allen, M.B., F.R.C.S. (consultant surgeon, Edgware General Hospital); J. A. Morgan-Hughes, M.D., M.R.C.P. (consultant neurologist, National Hospitals for Nervous Diseases and Bedford General Hospital); F. E. Loeffler, M.B., F R.C.S., M.R.C.O.G. (consultant obstetrician and gynaecologist, Central Middlesex and Willesden General Hospitals).

Universities and Colleges

BRISTOL

At a special degree congregation held on 13 July in the Great Hall of Bristol University on the occasion of the annual meeting of the B.M.A., the Chancellor, The Duke of Beaufort, conferred the degree of Doctor of Medicine *honoris causa,* on Mr. A. Lawrence Abel, Member of Council, B.M.A., Professor Hamid Ali M. Khan, Immediate Past-president, B.M.A., and Mr. Robert V. Cooke, President of the Association. The Public Orator was Professor T. F. Hewer, professor of pathology in the University. (Pictures in *Supplement,* pp. 83 and 85.)

CAMBRIDGE

[1]With honours. [2]With commendation.

LONDON

Professor P. C. C. Garnham has been appointed to the Heath Clark lectureship for 1968.

Dr. N. G. Trott has been appointed to the readership in physics as applied to medicine ten-

New Issues of Specialist Journals

BRITISH JOURNAL OF PREVENTIVE AND SOCIAL MEDICINE

Contents of the July issue are as follows:

Deliberate Self-poisoning in the Oxford Area. J. Grimley Evans.
Acute Poisoning and its Prevention. J. D. P. Graham and R. A. N. Hitchens.
Medical and Social Needs of Patients in Hospitals for the Mentally Subnormal. I. Leck, W. L. Gordon, and T. McKeown.
Indices of Obesity derived from Body Weight and Height. T. Khosla and C. R. Lowe.
A Community Study of Urinary pH and Osmolality. W. E. Waters, M. Sussman, and A. W. Asscher.
The Value of the Erythrocyte Sedimentation Rate as a Screening Test. G. Pincherle and J. Shanks.
Secular Changes in the Physique of Aberdeen Mothers, 1950–64. A. M. Thomson, W. Z. Billewicz, and R. M. Holliday.

Volume 21, No. 3. Yearly subscription (4 numbers) £3 3s., abroad £3 10s.

BRITISH JOURNAL OF OPHTHALMOLOGY

Contents of the July issue are as follows:

Pathology of Posterior Polymorphous Degeneration of the Cornea. Gwyn Morgan and Alan Patterson.
Iris Dysgenesis with Other Anomalies. R. A. D. Crawford.
Angle-closure Glaucoma and Inverse Astigmatism. J. McLenachan and D. F. C. Loran.
On a New Method to Cure Cataract by Extraction of the Lens. Jacques Daviel, translated by W. G. Pearce.
Surgical Safety of Prophylactic Peripheral Iridectomy. W. H. G. Douglas and Ian M. Strachan.
Idiopathic Acquired Lacrimal Drainage Obstruction. R. Dalgleish.
Visual Defects in Cases of Down's Syndrome and in Other Mentally Handicapped Children. P. A. Gardiner.
Cerebro-retinal Degeneration due to Carbon Dioxide Poisoning. David Sevel and Arnold Freedman.
Evaluation of Conjunctival and Nasal Bacterial Cultures before Intra-ocular Operations. John Nolan.
Keratoconus Posticus Circumscriptus with Indentation of the Lens. Hari Charan.
Choroidal Malignant Melanoma in a Child. Samuel T. Jones.
Plastic Reconstruction of the Upper Eyelid. S. V. M. Surya Rao, K. Vengala Rao, and C. Venkataramy Reddy.
Ophthalmological Synopses.
Crytoextractor and Cryopexor. M. M. S. du Toit.
Iris Retractor for Use with Cryoextractors. M. M. S. du Toit.
Reviews. Notes.

Volume 51, No. 7. Yearly subscription (12 numbers) inland £8 8s., overseas £9. With *Ophthalmic Literature* and Index (7 numbers) inland £15, overseas £16.

MEDICAL AND BIOLOGICAL ILLUSTRATION

Contents of the July issue are as follows:

Progress in Artificial Voice Aids. Bernard W. Watson.
A Bronchoscopist's View of Bronchial Anatomy. Peter Stradling.
Hyperbaric Oxygen Therapy: Its History and Current Scope. B. G. B. Lucas.
A Comparative Assessment of Optical and Fibre Gastroscopes. L. A. Kont and George Berci.
Deglutition in the Newborn. J. P Farriaux and G. Milbled.
An Experiment in University Teaching—Part I. G. E. Kenshole.
Schlieren Photography of an Ultrasonic Beam. Clive F. J Croot and Richard Robbins.
Audi Partem Alteram. Equipment and Methods. Journal Abstracts. Book Reviews. Motion Pictures and Other Media.

Volume XVII, No. 3. Yearly subscription (4 numbers) £3 3s., abroad £3 10s.

able at the Institute of Cancer Research, Royal Cancer Hospital.

The title of reader in anaesthetics has been conferred on Dr. M. K. Sykes in respect of his post at the Royal Postgraduate Medical School.

Correction

Thoracic Medicine.—We regret that Dr. D. A. J. Tyrrell's contribution to the recent conference at the Royal College of Physicians (1 July, p. 43) was inaccurately reported. The passage should have read as follows:

"At the second morning session the chairman Sir CHRISTOPHER ANDREWES, F.R.S., introduced Dr. D. A. J. TYRRELL (Common Cold Research Unit, Salisbury), who outlined the types of virus known to cause respiratory infection in man. Many of these were very selective in their choice of host cells, and their study had been simplified by the introduction of organ cultures of human respiratory epithelium. Dr. Tyrrell went on to classify respiratory viruses. The myxovirus group included the viruses of influenza, causing clinical influenza, but also colds, bronchitis, and bronchopneumonia; respiratory syncytial virus, causing bronchiolitis in infants and mild colds in older subjects; parainfluenza 1, causing croup, but also pneumonia and colds; parainfluenza 2, causing croup and minor respiratory infection; and parainfluenza 3, causing pneumonia and bronchitis in children, but mild colds in many cases.

Among other types, the rhinoviruses caused common colds and occasionally bronchitis, and the Coxsackie and adenoviruses mainly sore throats or feverish colds. Sore throats were often due to streptococcal infection. Respiratory viruses could survive in air for short periods only, and are spread most commonly by coughing and sneezing, but hardly at all during speech or normal breathing."

Deaths

Dart.—On 23 June 1967, in Launceston Hospital, George Herbert Dart, M.D., M.R.C.P.Ed., D.P.H., D.T.M.&H., aged 82.

Neumark.—On 12 July 1967, at St. Mary's Hospital, Paddington, Ernst Neumark, M.D., of 73 Lawn Road, London, N.W.3, aged 55.

Changed Character of Osteomyelitis

In the last 25 years the clinical picture of haematogenous osteomyelitis has changed dramatically for the better. As this period corresponds with the development and wider use of antibiotics, much of the credit has been given to them. Though some critics fear that the old cycle of fulminating septicaemic disease will begin again once there are sufficient antibiotic-resistant organisms circulating in the world,[1] antibiotics at present are the most potent weapon in the treatment of osteomyelitis, and their benefit has been enormous. The appropriate antibiotic will sterilize the bone abscess, thus reducing the local thrombosis in the bone and the size of the sequestra. As the small sequestra left after treatment may be absorbed, open sinuses and mixed infections have become rare. Massive sequestra are uncommon, and multiple recurrences of infection are now rare. The two conditions leading to a persistent sinus are a mixed bacterial infection in a cavity whose walls cannot collapse.

Whether antibiotics are responsible for all the present success of treatment is questionable, for whether in Europeans, Indians, or East Africans[2] the disease has changed to a less dramatic form. It is reasonable to assume that at least in advanced societies an improvement in the general health and hygiene of the community, particularly in infants and adolescents, has reduced the number of primary foci from which haematogenous osteomyelitis might spring. Minor infections are better treated, impetigo is rare, dental and tonsillar care is better. But these improvements alone do not suffice to explain the diminished severity of the disease in poorer populations. Clearly there are other factors at work, and they are not easy to explain.

While the more easily diagnosed septicaemic form accompanied by multiple foci of bone infection and positive blood culture has become rare, osteomyelitis in its modern subacute and benign form has become a trap for the unwary. Infantile osteomyelitis, though less common, may remain true to its old form. It is more often due to streptococcal infection than is adolescent osteomyelitis. Systemic disturbances are often less than the local physical signs would suggest, the disease being characterized by massive oedema of part of a limb and rapid separation of a large sequestrum, sometimes of the whole metaphysis of a long bone. This tragedy may have occurred before adequate antibiotic therapy has had time to act. A broad-spectrum antibiotic must be given at once in suspected cases without waiting to establish the correct one by laboratory studies.

In adolescence, still the most common age at which osteomyelitis develops, a subacute form of the disease is now more often seen than formerly. As before, the epiphysis remains the site of infection, the lower femoral epiphysis being most frequently attacked, and a history of trauma is still obtained in about half the cases. The onset is gradual. The patient is reluctant to use the limb, so that the physician may confuse the disease with early poliomyelitis or juvenile rheumatism. As the most

© *British Medical Journal*, 1967. All reproduction rights reserved.

serious error in the treatment of osteomyelitis is delay in the administration of an antibiotic, treatment should not await resolution of the doubt about the diagnosis. Better a cured child with an undiagnosed disease than a sick child with osteomyelitis. Radiology is of no value in establishing the diagnosis early, changes not usually being visible until between the seventh and tenth day. The important features are tenderness in the vicinity of an epiphysial line, local evidence of inflammation, especially oedema, and a raised erythrocyte sedimentation rate. The rise in the white cell count may be slight and delayed. True, an increase in the neutrophil/lymphocyte ratio may be more important as a diagnostic sign in the early stages, but it later returns to normal. Blood culture is negative in most cases. Estimation of the antibody titre is of little value.

Suspected cases must be given adequate doses of a broad-spectrum antibiotic and put at rest with local immobilization of the affected part. It is possible in some cases to abort the disease so effectively that the radiological evidence may be doubtful and merely consist of local rarefaction on the metaphysial side of the epiphysial plate. If the systemic manifestations of infection continue, it may be wise to change the antibiotic, but this will usually mean that pus has formed. Usually subperiosteal, it is indicated by an increase in the local oedema, and demands surgical incision. If subperiosteal pus is found, there is no need to drill the underlying bone; the medulla has become decompressed already. A specimen of pus should be taken in order to establish the appropriate antibiotic. The edges of the wound may be lightly drawn together, and after some delay it will usually heal with the minimum of scarring. Continuation of antibiotic therapy to avoid mixed infection and to prevent a recurrence of inflammation is necessary. Therapy should continue for a minimum period of four weeks after the onset of the disease.

Osteomyelitis in the adult from a cause other than injury is extremely rare, but it may be encountered in debilitating diseases, among which diabetes is well recognized. As L. R. I. Baker and his colleagues recently reported,[3] other debilitating diseases such as neutropenia secondary to systemic corticosteroid therapy may be rare precipitating causes, as also may hypogammaglobulinaemia.

Much remains obscure in the epidemiology of osteomyelitis, and further studies of its incidence in this and other countries are needed. While antibiotics have drawn its sting, their use does not wholly explain the changed pattern of the disease. They do need to be given early. Treated within the first three days, osteomyelitis may remain a benign disease.

Thyrocalcitonin

Thyrocalcitonin, or simply calcitonin, is a hormone that lowers the concentration of calcium in the plasma. Though it was discovered four years ago,[1] its significance in clinical practice remains uncertain. However, its source is now clearly recognized to be in the thyroid gland.

In a number of species, including man, two distinct types of thyroid cell can be recognized. The thyroxine-producing epithelial cells, arranged in acini or follicles, are familiar, but in addition there are cells of a different histological and histochemical type lying adjacent to the follicles but within the basement membrane. These have been variously known as "light cells," "parafollicular cells," "mitochondrion-rich cells," and "C cells." From studies using histochemical[2] and immunofluorescent[3] techniques there seems little doubt that these cells are the site of production of calcitonin. The mode of action of the hormone has also been determined. Experiments in vitro[4 5] and in vivo[6 7] indicate that calcitonin lowers the calcium level in the plasma by a direct action on bone, inhibiting bone resorption. The hormone also lowers the inorganic phosphate level in plasma and causes phosphaturia.[8] Hypercalcaemia is the stimulus for secretion of the hormone, and hypocalcaemia inhibits secretion. It would appear, therefore, that secretion of calcitonin is controlled by a feedback mechanism operating through the plasma calcium level[9] in a manner similar to that for the control of the secretion of parathyroid hormone, but in the reverse direction.

Thus much is known of the physiology of this hormone from experimental work. It is known too that human thyroid contains thyrocalcitonin.[10 11] Nevertheless, the role of thyrocalcitonin in disease in man and its possible usefulness in therapeutics have not yet been defined. G. A. Williams and colleagues,[12] studying totally thyroidectomized patients maintained on exogenous thyroxine, found them to have normal resting levels of calcium but an impaired ability to restore the calcium level to normal after an infusion of calcium gluconate. This suggests that calcitonin is more necessary for the control of hypercalcaemia than for the maintenance of a normal level of calcium. The place, if any, of calcitonin in the disturbances of calcium metabolism in thyrotoxicosis is not known, but there is evidence to suggest that the occasional hypercalcaemia seen in this disease is not due to impaired secretion of calcitonin.[13] In the report of the Clinicopathological Conference this week at page 293 a remarkable case is described in which a medullary carcinoma of the thyroid was associated with persistent diarrhoea. The functions of the C cells and their possible relationship to this syndrome are the subject of expert discussion by Professor A. G. E. Pearse, Dr. E. D. Williams, and Professor I. McIntyre.

Syndromes of hypersecretion of thyrocalcitonin might be expected to occur, but so far only isolated cases have been reported in which the findings were consistent with that possibility. In one[14] the patient presented with tetany and a diffuse non-toxic goitre. The serum calcium was 8.1 mg./100 ml. and biopsy of the thyroid showed an increase in the "parafollicular" cells. Extraction of the biopsy material yielded about 14 times more calcitonin than normal thyroid tissue. The serum calcium levels rose after total thyroidectomy. In a second case[15] the patient presented with recurrent thyrotoxicosis after thyroidectomy, and a serum calcium level which never exceeded 4.6 mg./100 ml. despite treatment with dihydrotachysterol, calcium, and extract of parathyroid. A second thyroidectomy was performed and the calcium levels rose after operation, thereafter being maintained at normal by small doses of dihydrotachysterol. It has also been noted that in cases of pseudohypoparathyroidism the calcitonin content of the thyroid is greatly in excess of normal,[16] [17] but it is not certain whether this is a primary event in the disease or merely represents an accumulation of calcitonin in the thyroid owing to chronic hypocalcaemia, a possibility for which there is experimental support.[18]

The therapeutic possibilities of the hormone would appear to lie in two directions—the treatment of hypercalcaemia and the treatment of excessive bone resorption. G. V. Foster and colleagues,[19] using purified pig thyrocalcitonin, lowered the plasma levels of calcium in patients with hypercalcaemia associated with bony metastases from breast cancer. The plasma calcium was lowered for 6–18 hours by one injection of the purified preparation. Since in most cases of hypercalcaemia (other than that due to hyperparathyroidism) the raised plasma calcium is not itself the major problem, the therapeutic possibilities in this direction are limited. Thyrocalcitonin might, however, prove useful in averting a parathyroid crisis in cases of severe hyperparathyroidism while preparations for surgery were being made. It may be added in connexion with hyperparathyroidism that, since calcitonin has been shown to have a phosphaturic action and is secreted in response to hypercalcaemia, C. J. Robinson and colleagues[8] have suggested that tests for hyperparathyroidism depending on phosphate excretion should not be used clinically.

Foster and colleagues[19] postulate a therapeutic role for calcitonin in cases of osteoporosis. At present the peptide nature of the hormone necessitates its being given by injection, which limits its usefulness, but more potent or longer-acting synthetic analogues might be produced in future which could prove useful in promoting the remineralization of bones depleted of calcium.

Problems of Transplantation

Extensive studies of the pathological changes that occur during the rejection of transplanted organs are still relatively few. One of the outstanding contributors to this field has been Professor K. A. Porter, of St. Mary's Hospital, so it is fitting that he should have edited the proceedings of a symposium held at the College of Pathologists[1] and now published as a supplement to the *Journal of Clinical Pathology.*[2]

Professor Porter's own contribution to the volume consists of a beautifully illustrated paper depicting the changes in transplanted kidneys when rejection occurs despite treatment of the recipient with immunosuppressive drugs. He describes four distinct patterns of rejection. First is an acute and immediate reaction within minutes of transplantation. Characteristic microscopical changes are glomerular microthrombi, with red-cell sludging. The lesion is thought to be due to circulating antibodies in pre-sensitized recipients or, when there has been severe blood-group incompatibility, between donor and host. The second form of rejection appears between two and ten days after transplantation. Cellular infiltration and rupture of peritubular capillaries are followed by tubular necrosis. This type of change is similar to that observed in experimental transplants in untreated animals. The third pattern of rejection occurs from 11 days onwards, and the main feature is vasculitis. Immunoglobulins and complement coat the arterioles and glomerular capillaries. Aggregates of platelets are found in the glomerular capillaries and fibrin thrombi in the walls of larger arteries. Organization of platelet thrombi results in narrowing of the interlobular arteries. The fourth type of rejection is insidious and can occur a long time after transplantation. There is subendothelial accumulation of immunoglobulin and complement on the glomerular capillary basement membrane, with progressive slow deterioration of renal function.

The two most promising recent advances in tissue transplantation—namely, the use of heterologous antilymphocyte serum and the application of tissue typing—were discussed by Professor M. F. A. Woodruff and Drs. J. J. Van Rood, A. Van Leeuwen, and J. W. Bruning. Professor Woodruff, who has pioneered the development of antilymphocyte serum, describes a serum prepared in the horse against human lymphocytes which has been used clinically by T. E. Starz and his colleagues. It would appear from preliminary result that this serum adds to the immunosuppressive action c azathioprine and prednisone without equivalent adde toxicity. Lower doses of prednisone can therefore be use with reduction in its unpleasant and even lethal side-effec when given in high dosage. Dr. Van Rood and his colleagu described two genetically independent leucocyte gro systems, one with ten and the other with two antigens. T antigens of the first leucocyte group system have been sho by skin-graft experiments to be transplantation antig Preliminary results suggest that matching of lymphoc groups of donor and recipient improves the chances successful kidney transplantation.

The remaining papers in this volume provide an excel background to the present state of knowledge of transpla tion immunity, particularly from the pathological poin view. Finally, in an authoritative summing up Prof Woodruff relates the experimental work to present cli results and future prospects in the field of transplantation. In addition to the problem of immunological rejection there are other difficulties, notably those in obtaining satisfactory numbers of donors, particularly from cadaver sources. Better methods of storing organs are also needed. Professor Woodruff ends with the hope that transplantation of organs from animals to man may eventually become successful.

[2] *Suppl. J. clin. Path.*, 1967, 20, ix–xv, 415–554. Published f College of Pathologists by the British Medical Association. 3

The College of Pathologists is to be congratulated on this symposium—the first it has held. The report of it provides an up-to-date account of tissue and organ transplantation which should be of help to all who are interested in this field, and particularly pathologists.

A Disease of Skin and Bowel

In the last 25 years occasional reports have appeared describing what is apparently a new disease affecting chiefly the skin and the intestines. The condition was first recognized in 1942 by R. Degos and his colleagues,[1] [2] who initially called it "atrophic papulosquamous dermatitis," and later[3] "malignant atrophic papulosis." An earlier report by W. Köhlmeier[4] which referred to a case of skin necrosis in a patient thought to have thromboangiitis obliterans clearly describes the same condition, and hence the name Köhlmeier–Degos disease has also been used.

The condition is rare. In a recent review W. E. Strole and others[5] found only 19 reported cases. The majority of these were from European countries, a few from the U.S.A., and one[6] from Great Britain. Seventeen of the patients were males, and of these 14 were aged under 40 years. The initial presentation is a papular skin lesion on the trunk and limbs. The papules are at first pink or grey, several millimetres in diameter, and appear in crops. They remain unchanged for some time, but later rapidly develop central umbilication and may coalesce to form larger lesions. With time they become less prominent and assume a rather mummified appearance, but they never disappear completely. At this stage the patient feels well, and, apart from the rash and transient burning or pruritus, has no symptoms. After a variable period, which may be weeks or years, abdominal pain, weakness, fatigue, loss of weight, and sometimes diarrhoea develop. Intestinal perforation then follows and in most cases it is fatal, because multiple perforations occur either simultaneously or at intervals. At laparotomy or necropsy the bowel wall is seen to be studded with multiple depressed white patches similar to the skin lesions. In three cases death was due to multiple cerebral infarcts.

Histologically the characteristic lesion is a change in the rterioles and small arteries. The affected vessels are occluded y relatively acellular fibrous thrombi, and the wall of the rtery at the site of occlusion shows a subendothelial fibrolasia. The elastic lamina remains intact and at this level ere is no inflammatory response either in the vessel wall in the periarterial tissues. Elsewhere in the artery, hower, an arteritis resembling that seen in polyarteritis nodosa ay be found. Though clinically the disease presents mainly th skin and intestinal lesions, the arterial changes are in fact widespread and may be in any organ. The skin lesion is a non-specific combination of epidermal atrophy and dermal sclerosis, and the histological diagnosis rests on finding the characteristic vascular lesion in the small arteries of the reticular dermis.

Laboratory investigations do not reveal any specific changes. The course of the disease appears to be uniformly fatal, and so far all the therapeutic regimens which have been tried have failed.

Is this a new disease ? From the published descriptions of the illness the clinical picture is apparently striking and it is unlikely that it would not have been recognized and reported by the astute clinicians of the early years of this century. The condition which it most closely resembles is polyarteritis nodosa. The clinical picture with the emphasis on the skin and the intestines is certainly unlike classical polyarteritis nodosa. Though the main lesion in the small arteries is apparently different from that of polyarteritis, yet some of the published photomicrographs do show a distinct arteritis in parts of the affected vessels. The time course of the illness and the lack of response to adrenal corticosteroids also suggest that though "malignant atrophic papulosis" is primarily a disease of small arteries and arterioles it may be distinct from polyarteritis nodosa. But it seems equally possible that, like Wegener's granulomatosis, it is a variant of a disease with protean manifestations.

A Case for Cannabis?

The full-page advertisement in *The Times*[1] signed by prominent scientists, doctors, and intellectuals, urging that "the law against marihuana is immoral in principle and unworkable in practice," is only one of many recent appeals[2] in Britain and the U.S.A. for a more permissive attitude.

Marihuana, "pot," and hashish are all forms of cannabis, and are obtained from the flowers or leaves of the female Indian hemp plant, *Cannabis sativa.* International legal control of cannabis came into being in 1925, when the League of Nations organized its second opium conference.[3] The Egyptian delegate stated that 30 to 60% of the patients suffering from insanity in Egypt were cases of chronic hashishism. The conference agreed that the use of Indian hemp and its products should be authorized for medical and scientific purposes only, and that international trade should be strictly controlled. In Britain the Dangerous Drugs Act of 1920 was amended to include cannabis, and it is still included in the 1965 Act.

Cannabis has no known therapeutic value,[4] and possibly as a result of this there has been little research into its pharmacology in man. Inhaled smoke produces initial effects within a few minutes and maximum response is obtained in half to one hour, persisting for some three to five hours. If the drug is taken in a conducive setting its effects commonly include tranquillity, apathy, and euphoria. Much less frequently fear, aggression, and hilarity are noted, these sometimes being seen when cannabis is used by an extrovert in a stimulating situation. With increasing doses changes in mood are followed by changes in perception including changes in perception of the passage of time and then by hallucinations. There is also an idiosyncratic reaction resembling a psychosis ; this is not dose-dependent, and the probability of its occurrence is apparently not related to the stability of the personality. Rarely hallucinations and fragmentation of thought processes occur and present as psychotic disturbances. The physical signs may include variations in blood pressure and pulse rate, bronchoconstriction, hypoglycaemia, and alimentary disturbances, though these features are not constant. More significant is the marked dilatation of conjunctival blood vessels which frequently occurs after first taking the drug.

The World Health Organization has defined a state of drug dependence of the cannabis type.[5] There is a moderate to strong psychological dependence as a result of a desire for the subjective effects, but an absence of physical dependence—so no abstinence syndrome occurs—and there is no evidence of tolerance. Commenting on this, N. B. Eddy and his colleagues stated that individuals dependent on cannabis might suffer from " inertia, lethargy, self neglect, feelings of increased capability with consequent failure, and precipitation of psychotic episodes."

Research into the effects of cannabis in man is in progress in the U.S.A. and elsewhere.[6] No objective assessment of the effects of prolonged administration of the drug has yet been published. There is still disagreement whether or not cannabis users are likely to progress to heroin and other " hard " drugs. An answer to both these questions is urgent. But while the effects of prolonged exposure to cannabis remain speculative it is irresponsible to encourage a more permissive attitude to the drug.

Respiratory Burns

On 28 November 1942 a disastrous fire occurred at the Cocoanut Grove night club in Boston in which 491 people lost their lives. Of the 114 casualties taken to the Massachusetts General Hospital, 75 were either dead on arrival or died of anoxia within minutes. Of the 39 who survived long enough to be treated, only three were entirely without respiratory symptoms. The clinical picture,[1] *x*-ray appearances,[2] and pathology[3] of these pulmonary injuries were well recorded. Only a small proportion of the victims had extensive burns, and most of the deaths were attributed to anoxaemia and poisoning by carbon monoxide and traces of oxides of nitrogen.

In 1945 A. R. Moritz[4] and his co-workers published experimental work on dogs in which they showed that when hot air was blown into the larynx at 270° C. the temperature of the air fell to 50° C. in the trachea. Hot air and flame could burn the larynx and trachea but failed to produce pulmonary damage. On the other hand, inhaled steam produced severe pulmonary injury owing to its greater latent heat.

A review by A. W. Phillips and colleagues of cases treated at the Massachusetts General Hospital during 1939–57[5–7] showed that in 42% of fatal cases the patient died of damage to the respiratory tract, about half of these in the first three days. They stressed the significance of deep flame burns around the nose and mouth, burning in an enclosed environment, and the inhalation of smoke and the products of incomplete combustion as ominous warning signs of pulmonary damage even in the absence of respiratory signs and symptoms.

Recently H. H. Stone and his colleagues,[8] dissatisfied with the results of treating patients with pulmonary burns (mortality 89%), carried out experiments to evaluate present methods of therapy. They insufflated steam at 10 mm. Hg pressure through a chilled, plastic, intratracheal tube for one to five second in rats. Their studies showed that treatment with 40% oxygen or 80–100% humidity reduced the mortality of the animals. Antibiotics failed to decrease mortality, and treatment with adrenal steroids appeared to be contraindicated.

Respiratory tract damage in burned patients is less common in Britain than in the United States. In Britain extensive burns affecting the face are usually the result of clothes being set alight from unguarded coal fires, and not from people being trapped in burning buildings. The victims, usually children, run about breathing normal air till the flames are put out. In this country only about 5% of patients admitted to hospital with domestic burns have received them in conflagrations, and a pulmonary lesion, because it is uncommon, tends to be missed until a disaster like the Dellwood Maternity Home fire,[9] which killed 13 newborn babies, reminds us of the truism that " smoke is poison."

Clinically, the surgeon should suspect damage of the pulmonary tract from the circumstances in which the patient was burned. He must then assess the site of the damage. If the pharynx, larynx, and upper trachea alone are injured the patient will probably complain of a sore throat and hoarseness—possibly leading to stridor. He may also have a cough, with carbon particles in the sputum and perhaps flecks of blood. If pulmonary damage is present it may not be apparent for several hours, or it may kill the patient with anoxia in a matter of minutes.

Stone's classification of pulmonary damage into respiratory insufficiency, pulmonary oedema, and pulmonary infection is a practical one ; the first two stages may not be clinically obvious in a mild case.

Pulmonary insufficiency may last 24–36 hours. It is the result of narrowing of the smaller bronchi due to spasm, congestion, and oedema of the walls, and blocking with carbon particles, epithelium, fibrin, leucocytes, and mucus. This leads to laboured breathing with an expiratory wheeze. Anoxia is evident from restlessness and confusion, and it may lead to coma and permanent brain damage. Cyanosis is usual, but it may be masked by anaemia or the cherry-red of carbon monoxide poisoning. If rales are present within an hour the prognosis is grave, but even if they are absent the victim should be admitted to hospital overnight for observation like a case of concussion. A single normal chest radiograph is of no significance. Changing physical signs in the chest are probably due to transient atelectasis and filling of alveoli with exudate, epithelial debris, and white cells. Stone's work has shown the value of treating burned patients in this stage with 40% oxygen and 80–100% humidity. Positive-pressure ventilation did not appear to overcome hypoxia, and tracheostomy, except for associated laryngeal obstruction, may precipitate pulmonary oedema by reducing the intrapulmonary pressure produced by intermittent glottic obstruction to respiration. Aminophylline may help to relieve bronchospasm.

Pulmonary oedema, which is uncommon within eight hours of the burn, usually follows resuscitation. Strictly aseptic positive-pressure ventilation is the only useful therapy[8] and may be given through a tracheostomy, cuffed tube, or face-piece. Pulmonary infection is the final condition through which all cases of pulmonary damage must pass, and it calls for antibiotics in high dosage controlled by daily cultures.

First aid for scalds has been in the public eye in recent months, particularly in the controversial matter of immediate cooling of the scalded skin. But there is no controversy about the value of a first-aid precaution against smoke and toxic fumes. The three survivors of the Cocoanut Grove disaster who sustained no damage to the respiratory tract had covered their mouths with wet clothes. Is this not a measure which television playwrights could teach by portrayal without comment ?

Sjögren's Syndrome

If a woman in her 40s complains of dry, smarting, burning, or itching eyes and a dry mouth, then the possibility of Sjögren's syndrome[1] should be considered. The other common component of the syndrome is rheumatoid arthritis, but this may be replaced or overshadowed by enlargement of the parotid or lacrimal gland, purpura, Raynaud's phenomenon, subcutaneous nodules, dry skin, scleroderma, splenomegaly, or peripheral lymphadenopathy.[2] Thus the patient may be seen in either the ophthalmic or the rheumatology clinic, thereby determining which set of investigations will be undertaken. The ophthalmologist will insert Schirmer filter paper inside the lower eyelid near the external canthus to demonstrate deficiency of lacrimal secretion ; a drop of rose-bengal dye to demonstrate obvious staining of the bulbar conjunctiva and cornea ; and he may find, by slit-lamp examination, punctate corneal staining with fluorescein. By these means the presence of kera-conjunctivitis sicca may be confirmed. The rheumatologist, on the other hand, will seek confirmation of the clinical diagnosis of rheumatoid arthritis by radiological and serological examinations. It is particularly the field of serology which has contributed richly to our knowledge of the disorder and extended the perspectives of its aetiology and pathogenesis. B. R. Jones[3] found that the sera of patients with Sjögren's syndrome contained specific precipitating antibodies reacting with extracts of salivary and lacrimal glands, while J. R. Anderson and his colleagues[4] detected non-organ-specific precipitating autoantibodies reacting with a variety of extracts of human and some animal tissues and thyroglobulin. Serological tests suggestive of systemic lupus erythematosus are also a feature of Sjögren's syndrome. J. M. Heaton[5] demonstrated the frequent occurrence of the lupus-erythematosus cell test, subsequently showing with D. Doniach that the antinuclear factor and thyroid autoantibodies occurred in about a half of patients with Sjögren's syndrome. The rheumatoid factor was found in 82% of cases ; it was present in the same proportion whether or not there was joint disease.[6] In a still wider clinicoserological survey in Bethesda in the United States evidence was found not only of distinct clinical but also of serological subgroups.[7] The presence of rheumatoid factors in almost every case of Sjögren's syndrome, even in the absence of rheumatoid arthritis, was an unexpected finding.

All the evidence points to the fact that Sjögren's disease is an autoimmune phenomenon, and the pathological findings support this view. Thus lacrimal and salivary glands are infiltrated by lymphocytes and plasma cells, with atrophy of the secreting acini and increased interstitial fibrosis. Similar infiltrative changes are widespread, as might be expected in a disorder which has a chameleon-like variety of clinical masquerades. Moreover, though the syndrome may present and be investigated in ophthalmic and rheumatology clinics, it may be found by diligent search in patients seen in psychiatric and gastroenterology clinics. Sjögren's syndrome is predominantly a disorder of menopausal women, many of whom are also suffering from endogenous or reactive depression. It may occur simultaneously with another autoimmune process—primary biliary cirrhosis—which is also common in women in their 40s. Under these circumstances depression and primary biliary cirrhosis may prove dominant and mask concomitant Sjögren's disease unless the serological abnormalities of the latter are specifically sought.

It remains a distressing affliction since treatment is so unsatisfactory. Local treatment to the eyes for relief of symptoms due to dryness includes 1% methylcellulose in saline (artificial tears) or sulphacetamide eye drops. The latter are bland and alkaline and minimize bacterial complications. The danger of corneal ulceration is always present, so that corticosteroid drops should incorporate an antibiotic. Sealing of the puncta by cautery helps to conserve what little moisture is present, and contact lenses may give relief if these are tolerated. Because of its similarities to rheumatoid arthritis and systemic lupus erythmatosus, J. M. Heaton[8] conducted a double-blind trial comparing the value of giving 800 mg. hydroxychloroquine daily for six months with a placebo. A significant difference was obtained, for 12 of 15 improved with hydroxychloroquine compared with 6 of 15 while on the placebo. Two patients developed toxicity owing to deposition of the drug in the cornea, which took two months to appear and about five months to disappear after the six-month course of hydroxychloroquine had ended. Antimalarial drugs are particularly indicated if an appreciable degree of rheumatoid arthritis is also present. Because of its putative autoimmune nature the syndrome has also been treated by immunosuppressive drugs. Thus corticosteroid drugs have been used both locally and by mouth, but relapses have followed cessation of treatment and the danger of corneal ulceration is a real one. Since it commonly occurs in menopausal women, oestrogens might be found to be helpful ; and this association is strengthened by the fact that excretion of hydroxyproline, which is greatly raised in Sjögren's syndrome, may be corrected by oestrogen administration. If the depression is endogenous rather than due to the distressing affliction itself, then a therapeutic trial of nortriptyline or imipramine is worthwhile.

Psychiatric Sequelae of Subarachnoid Haemorrhage

P. B. STOREY,* M.B., M.R.C.P., D.P.M.

Brit. med. J., 1967, 3, 261–266

This study is a report on the psychological and psychiatric morbidity of 261 cases of subarachnoid haemorrhage treated at Atkinson Morley's Hospital between January 1958 and June 1964. During this period approximately 2,750 patients with subarachnoid haemorrhage were admitted, in about 1,300 of whom aneurysms were demonstrated. Many of the latter were included in a trial of surgical versus nonsurgical treatment in patients with ruptured cerebral artery aneurysms, the organization and early results of which were described by McKissock, Richardson, and Walsh (1960). The background to the trial was that, although surgery of various types had been used for many years, there was no clear knowledge of the natural history of patients with ruptured aneurysms, so that the surgical results reported were possibly due to selection of cases already out of danger from rebleeding (McKissock and Walsh, 1956 ; Norlen and Barnum, 1953).

The trial was designed to allocate cases suitable for surgery randomly to operative or conservative treatment after stratification by site of aneurysm, blood pressure, age, clinical condition, and elapse of time since the haemorrhage. Sex was not originally used as a stratification factor, but it was realized later (McKissock, Richardson, and Walsh, 1962) that it was of great importance in middle cerebral aneurysms, as women fared worse with surgery than did men.

Conservative treatment in this trial means six weeks' rest in bed, with any necessary medical measures, including hypotensives, followed by gradual mobilization. Surgical treatment is of three main types: common carotid ligation (C.C.L.) ; direct attack on the aneurysm (D.A.) ; and proximal occlusion of the vessel from which the aneurysm arises, used only for anterior communicating aneurysm in this series. The operations used in the cases considered in the comparisons are described later.

The results of the trial of surgery so far have been published by McKissock, Richardson, and Walsh (1960, 1962, 1965) ; they indicate that surgery is of definite benefit in posterior communicating (P.C.) aneurysms and in men with middle cerebral (M.C.) aneurysms. No significant differences between operative and conservative treatment have been shown for women with M.C. aneurysms or for patients with anterior communicating (A.C.) aneurysms.

The risk of rebleeding from a ruptured cerebral artery aneurysm is greatest in the first few days, and is quite small after two weeks. Surgery to be of real value must therefore be used in the early stages.

There are many scattered references to various psychiatric complications in the literature, but no comprehensive study has been found. All who work in this field are aware that in a certain number of cases marked personality and intellectual deterioration may occur, and that anxiety and depression are not uncommon late results. Walton (1956) in his well-known book on subarachnoid haemorrhage said that mental symptoms proved to be an important cause of disability in his series of patients, both from organic brain damage and from anxiety symptoms ; and commented that such sequelae had received little attention in the literature.

Present Study

Material

Follow-up has been made of 261 patients with proved subarachnoid haemorrhage. All were seen between December 1963 and June 1965. Selection was made without knowledge of their clinical state ; but some patients with an aneurysm in a certain site were chosen in order to bring the groups up to approximately equal size. There was no other special selection.

The follow-up period varied between six years and six months: it was more than three years in 145, between three years and 18 months in 43, and less than 18 months in 73. In only 11 was the follow-up period less than one year ; two of these were at six months, and none was at less than six months.

The age of the patients varied from 19 to 67 years: 6% were under 30 years, 25% were from 30 to 44, 50% were from 45 to 59, and 20% 60 or more.

Of the 261 patients seen seven had multiple aneurysms and 30 had no aneurysms. None was believed to have had a primary intracerebral haematoma, nor had any had a head injury. None of the patients had been on M.A.O. inhibitor drugs at the time of haemorrhage, so far as is known. The remaining 224 had single aneurysms, 81 anterior communicating (A.C.), 72 posterior communicating (P.C.), and 71 middle cerebral (M.C.) aneurysms. Fifteen of those with single aneurysms were for technical reasons regarded as unsuitable for the trial or had an operation in order to evacuate a life-threatening haematoma. These and the seven patients with multiple aneurysms are not considered further here.

When the study was carried out all cases with A.C. aneurysms and women with M.C. aneurysms were still in the trial if they fulfilled the criteria, but those with P.C. aneurysms and men with M.C. aneurysms had been out of the trial, and therefore treated operatively, since 1959 and 1961 respectively. To increase the size of the groups under comparison all cases in the two latter categories have been included in the "trial comparisons" if they fulfilled the original trial criteria—even if they were admitted after the trial had been abandoned—and surgery recognized as the treatment of choice. Such cases are described as suitable for trial in this paper. Of the 224 patients with single aneurysms 163 were actually in the trial and a further 46 were suitable for trial (but all were treated surgically). There are consequently 209 patients who may be used to provide valid comparisons of the incidence of psychiatric and other sequelae—in 125 operatively and 84 non-operatively treated cases. Table I shows the sex and treatment distribution. Of the 30 cases with no aneurysm 14 were men and 16 women.

* Senior Lecturer in Psychiatry, St. George's Hospital Medical School, London S.W.1. Supported by grant number NB 03138-06 from N.I.H., Bethesda, Maryland, U.S.A., during course of the study.

In order to check the validity of the comparisons between the 125 operatively treated and 84 conservatively treated cases a series of χ^2 estimations was made on the incidence of the following 11 pretreatment factors in the two groups: sex; age; side of aneurysm; coma following the haemorrhage; level of consciousness on admission (alert or not alert); the incidence and severity of lateralizing neurological signs; blood pressure on admission (above 160/90 or not); incidence of haematomata and of cerebral arterial spasm on angiography; history of previous subarachnoid haemorrhage; and the results of carotid compression before angiography. No significant differences emerged, either between these two groups or in the distribution of the factors between operative and conservative subgroups for each type of aneurysm separately. They may therefore be justifiably compared for the results of treatment.

C.C.L. = Common carotid ligation. D.A. = Direct attack on aneurysm after craniotomy, with clipping or gauze wrapping of aneurysm. Proximal occlusion = Of the supplying vessel.

Methods

Of the 261 cases 260 were seen by me, all but eight in their own homes.[1] In 242 cases another informant was also seen, usually the spouse or other close relative.

Each interview lasted between one and a half and two hours, and consisted of an initial informal period with the patient, followed by history-taking and then by questions from a check list. Simple clinical tests of memory, grasp, and comprehension were used. Lastly, the Benton visual retention test and the Inglis paired-associate-learning test were given in most cases. The patient then laid down, and the relative was interviewed separately. The patient was finally examined physically, and blood pressure was measured at the beginning and end of the examination, the lower reading being accepted. Minor lateralizing neurological signs were carefully looked for as presumptive evidence of brain damage.

In addition to interview material letters from the patient in answer to earlier routine follow-up inquiries were studied, and in many cases letters from the patient's general practitioner were also available. A few general practitioners were seen personally—mainly in rural districts. With regard to patients who had had hospital psychiatric treatment the hospitals concerned were contacted, notes being forthcoming in most cases.

At the end of the interview ratings were made on four scales—physical disability, psychiatric symptoms, personality impairment, and intellectual impairment. These are described in the Appendix, and all were made within a few minutes of the end of the interview. (In some cases where other hospital notes were studied later the rating for psychiatric symptoms was changed.) Unfortunately no rating was made on overall mental disability at that time, but during analysis of the results it was realized that such a rating was necessary. As many patients were rated as impaired on more than one of the scales, a false impression could be gained by mentally summing the scores arithmetically. Rating scales of this type are not entirely suitable for such summing, as no truly mathematical relationships can be assumed. A five-point scale of overall mental disability was therefore constructed, the original notes were scrutinized again, and each patient was rated on the scale (see Appendix for details). This procedure has the advantage that more valid comparisons can be made on overall disability and, most importantly, each patient is being considered only once in the comparisons. It is obvious that these last ratings were made after the results were already clear, but every attempt was made to avoid bias.

Results

1. Overall Mental Disability

With the use of the five-point scale as a measure of overall mental disability (see Appendix), Table III shows the results in the 209 aneurysm cases used in the trial comparisons. Comparable figures for the 30 cases with no demonstrated aneurysm are also given.

TABLE III.—*Results in* 209 *Aneurysm Cases* (*Trial Comparisons*) *and* 30 *No-aneurysm Cases. Overall Mental Disability*

	Absent	Mild	Mod.	Severe	V. Severe	Totals
P.C. ..	33 (51)	15(23)	11 (17)	6 (9)	0 (0)	65 (100)
M.C. ..	26 (38)	14 (21)	12 (17)	11 (16)	5 (7)	68 (99)
A.C. ..	35 (46)	22 (29)	14 (18)	3 (4)	2 (3)	76 (100)
All an. ..	94 (45)	51 (24)	37 (18)	20 (10)	7 (3)	209 (100)
No an.	19 (63)	8 (27)	2 (7)	1 (3)	0 (0)	30 (100)

Percentages in parentheses.

Comparing all those with aneurysms with those without, and simplifying the results into absent/mild and moderate/severe/very severe, we find that morbidity is significantly greater in those with aneurysms ($\chi^2 = 5.593$ with 1 degree of freedom, $P < 0.02$).

Those with M.C. aneurysms do worse than those with A.C. or P.C. aneurysms. Again simplifying Table III as above, and considering only the aneurysm cases, then $\chi^2 = 5.345$, $P < 0.1$ with 2 degrees of freedom, not quite reaching conventional levels of significance. If, however, M.C. aneurysms are compared with the others as a whole, then $\chi^2 = 5.320$, $P < 0.05$ with one degree of freedom.

The distribution of central nervous system signs at follow-up is shown in Table IV, but the findings on admission are omitted to save space.

---

[1] One case is included on the basis of detailed letters from the patient and his wife, and of a report from Wing Commander A. W. Black, R.A.F., who examined him, and to whom I am indebted. (The patient was rated unimpaired in all respects.)

In patients with aneurysms the neurological signs at follow-up were significantly more frequent and severe than on admission ($\chi^2=6.30$, $P<0.02$, with one degree of freedom). In those without aneurysms the incidence of the neurological signs was almost exactly as on admission. The fact that no increase occurs in the signs of the no-aneurysm cases indicates that the ratings are probably reliable, as these latter patients have very low rebleed rates, and no possibility of postoperative complications. (The ratings of C.N.S. signs on admission are derived from surgical notes made by a number of people over several years, whereas the follow-up examinations were all made by me.)

There is a significant difference in the incidence of neurological signs at follow-up in the three main aneurysm groups, being greatest in those with M.C. and least in those with A.C. aneurysms. (When grouped as absent/mild and moderate/severe $\chi^2=8.407$ with 2 degrees of freedom, $P<0.025$.)

The fact that those with M.C. aneurysms have a higher incidence of signs is at least a partial—and probably a complete—explanation for their increased overall mental morbidity, demonstrated in Table III. Equally, those with no aneurysms have the fewest neurological signs and the lowest mental disability, while those with A.C. and P.C. aneurysms have intermediate positions in these respects. The evidence is not set out fully in this paper, but, as would be expected, both personality and intellectual impairment are clearly associated with brain damage, of which neurological signs are unequivocal evidence. Psychiatric symptoms of anxiety and depression are not infrequent in those without neurological signs, but those with brain damage have a greater tendency to such symptoms than those without.

TABLE V.—*M.C. Aneurysms in Trial Comparisons. Overall Mental Disability*

	Absent	Mild	Mod.	Severe	V. Severe	Totals
			(a) Women			
R Op. ..	4	3	2	0	1	10

L Op. ..	1	2	2	4	2	11
L Cons.	4	2	1	1	1	9
Totals	13 (32)	11 (27)	7 (17)	5 (12)	4 (10)	40
			(b) Men			
R Op. ..	4	1	3	4	0	12
R Cons.	2	1	1	2	0	6
L Op. ..	3	1	1	0	1	6
L Cons.	4	0	0	0	0	4
Totals	13 (46)	3 (11)	5 (18)	6 (21)	1 (4)	28

There were no significant differences between the overall mental disability of the operatively and the conservatively treated groups, between men and women, nor between those with right-sided as opposed to left-sided aneurysms. A.C. aneurysms are essentially midline structures, although they may damage one side of the brain more than the other on rupture; they are therefore not included in this comparison.

Although when the trial material is considered as a whole there are no sizable differences between operative and conservative groups, between men and women, or between right- and left-sided aneurysms, this is not so when those with M.C. aneurysms are considered separately. Patients with M.C. aneurysms do worse overall than those with other aneurysms (Table III), and it can be seen from Table V that this is entirely because of the worse results with surgery in this group. The difference is most pronounced in the case of women with left-sided aneurysms, but men with right-sided aneurysms also fare worse with surgery than with conservative treatment.

Table V (*a*)—that is, for women with M.C. aneurysm—has been analysed using Cochrans's criterion, testing for the difference in mental disability when grouped as absent/mild and moderate/severe/very severe, and correcting for the differences between right- and left-sided lesions. The test is two-tailed, and the result is between the 7% and 8% levels of significance ($t=1.778$), not quite reaching conventional levels.

Table VI shows M.C. aneurysm cases of both sexes, divided by type of treatment for added clarity.

TABLE VI.—*M.C. Aneurysms in Trial Comparisons. Operative versus Conservative Treatment*

	Absent	Mild	Mod.	Severe	V. Severe	Totals
Op. ..	12 (31)	7 (18)	8 (21)	8 (21)	4 (10)	39 (101)
Cons. ..	14 (48)	7 (24)	4 (14)	3 (10)	1 (3)	29 (99)
Totals ..	26 (38)	14 (21)	12 (17)	11 (16)	5 (7)	68 (99)

Combining the results into two categories of absent/mild and moderate/severe/very severe, the latter contains 52% of the operative and only 27% of the conservative groups. The use of χ^2 test shows the difference to be significant at the 5% level. ($\chi^2=3.892$, $P<0.05$ with one degree of freedom.)

Comparable separate tables for A.C. and P.C. aneurysm groups are not given, but in fact those treated by surgery have a lower overall mental disability than the conservatively treated patients. The differences are not significant. They are, however, marked enough to even out the operative versus conservative comparisons when all aneurysms are considered together.

2. Using Separate Rating Scales

The results so far have been set out with the use of only the rating of overall mental disability. As was explained earlier, each patient was originally rated on four scales, each of four points, for personality impairment, psychiatric symptoms, intellectual impairment, and physical disability (see Appendix). These are set out as histograms in Figs. 1 and 2. It must be remembered that in the overall mental disability ratings psychiatric symptoms were given relatively less weight, as in

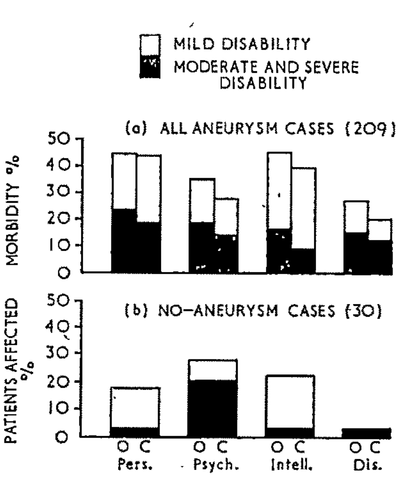

FIG. 1

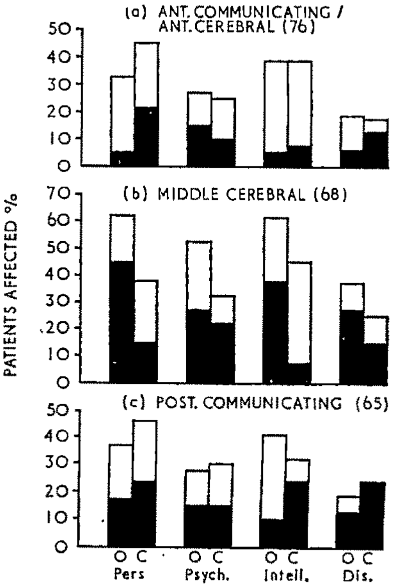

FIG. 2

FIG. 1.—All aneurysm cases in trial comparisons. O—Operated cases. C—Conservative. Pers.—Personality impairment. Psych.—Psychiatric symptoms. Intell.=Intellectual impairment. Dis.—Physical disability. FIG. 2.—Comparison of major aneurysm groups.

many cases they are transient, whereas personality and intellectual impairment are permanent. The histographic method, with four point-rating scales, makes differences between groups more apparent than did the overall rating method, but there are no major inconsistencies. The rating scales were also assessed statistically, using *t* tests, and the results of these will be mentioned where applicable. Fig. 1 shows that the aneurysm cases are more severely affected than those with no aneurysm, and also shows that in the latter group there is very little personality impairment, intellectual impairment, or physical disability rated as moderate or severe. One man, the only no-aneurysm case with C.N.S. signs rated moderately severe at follow-up, is responsible for the 3% shown in each of those categories. Patients with no aneurysms have, however, a similar incidence of psychiatric symptoms to patients with aneurysms. Seven of the 30 patients without aneurysms had clinically significant anxiety or anxiety/depressive states at the time of their haemorrhage, but only two out of seven are rated here as being worse than before the stroke. (This aspect will be dealt with in greater detail in a later publication.)

The columns representing the aneurysm cases in Fig. 1 show a slight worsening in the operative groups, which did not appear in the ratings of overall mental morbidity, but the differences are not significant.

Fig. 2 shows the results in the three main aneurysm groups, from which it can be seen that in the P.C. and A.C. cases those treated operatively do somewhat better than the others, but the differences are not significant. M.C. cases do considerably worse with surgery, however, particularly where moderate damage and severe damage are concerned. Using *t* tests, and considering the sexes and side of aneurysm separately (although the histograms do not show them separately), the significant differences are as follows: for personality impairment in women with left-sided aneurysms, operative cases do significantly worse than conservative cases at the 1% level ($t=2.9$, $n=17$, $P<0.01$); for intellectual symptoms in the same cases the difference is significant at the 2% level ($t=2.8$, $n=17$, $P<0.02$). None of the other differences reach conventional levels of significance.

3. "Improved Personality"

Details of the nature of the personality and intellectual impairment, and of the psychiatric symptoms, will be reported elsewhere, but there are some points which may suitably be mentioned here.

Depressive and anxiety states occurred in patients with and without brain damage, and in this study those with brain damage are rated as depressed even if there is no evidence of depressive illness, and if in my opinion the mood change was distinctive enough. In this way a number of those rated as having mild psychiatric symptoms showed a picture of shallow depression, easily lifted, in a setting of personality and intellectual impairment.

The personality changes which occurred were mainly those commonly recognized in brain damage, but 13 patients were regarded as having improved personalities. (They were rated unimpaired in the results already discussed.) Eight of the 13 had an A.C., four had a P.C., and one had an M.C. aneurysm. This description of "improved" depended essentially on the account of the patient's spouse, which was available in each case. Such a patient was typically described as being more pleasant to live with, a nicer person, less sarcastic and irritable, less tense and anxious, less fussy and overmeticulous, and often as more affectionate and tolerant. Two of the patients showed minor forgetfulness, but in none was there any loss of drive, any falling off in work ability, or any untoward development. None had experienced any depressive or anxiety symptoms, and most were aware of increased well-being subjectively. In seven cases there were no abnormal C.N.S. signs, and in six there were mild or moderate signs. There were no differences between operative and conservative groups in these cases. The previous personality of these patients was described in each case in such terms as "cold," "tense," "sarcastic and irritable," "unreasonably houseproud," or "timid and worrying." Naturally there were a good many patients in whom similar changes were associated with unfavourable changes, and who are therefore not described as having improved.

4. Epilepsy

In the whole case material of 261 patients there were 22 who had had epileptic disturbances. These all had either an M.C. aneurysm (17 cases out of 71, or 24%) or a P.C. aneurysm (five cases out of 72, or 7%). The overall incidence of epilepsy in those with single aneurysms was therefore 22 out of 224 cases, or approximately 10%. The epilepsy was easy to control in all except four patients, and in most there were only a few fits.

There are no significant differences between the operative and conservative groups, but epilepsy is significantly more common in men than in women ($\chi^2=8.556$, $P<0.01$ with one degree of freedom) and with M.C. aneurysm than with P.C. aneurysm ($\chi^2=5.685$, $P<0.025$ with 1 degree of freedom). None of the other differences is significant.

Epilepsy was in all but six cases associated with some abnormal neurological signs, mostly moderately severe or severe, and some other mental disability was present in all but five cases. Fourteen of the 19 patients with epilepsy had had a haematoma demonstrated by angiography—an incidence of 74%. Overall 40% of all patients with M.C. and P.C. aneurysms had haematomata.

Discussion

Subarachnoid haemorrhage from ruptured cerebral artery aneurysm is not uncommon, having been estimated at 6 per 100,000 of population in the area served by Atkinson Morley's Hospital (Crawford and Sarner, 1965). Among patients reaching hospital alive the subsequent mortality depends on various factors—particularly clinical condition, level of consciousness, site of aneurysm, age, blood pressure, and others—(McKissock *et al.*, 1960, 1962, 1965; Richardson, Jane, and Payne, 1964; Richardson, Jane, and Yashon, 1966). In this study the operative and conservative groups were shown to be comparable for the factors named, as well as for various others. The mortality after admission to hospital is high; in the studies mentioned the six-month survival rates of operatively and conservatively treated cases combined were approximately: P.C. aneurysms 69%, M.C. aneurysms 72%, and A.C. aneurysms 58%.

This study shows that the psychiatric morbidity of the survivors is also high. Only 45% of those in the trial comparisons were considered to be unimpaired and 24% as mildly affected. Eighteen per cent. were moderately, 10% severely, and 3% very severely damaged—these last being demented and inaccessible. M.C. aneurysm is associated with a significantly higher morbidity than either of the other main aneurysm types, and most of the serious mental disability was associated with neurological evidence of brain damage. Depressive and anxiety states, sometimes very severe, were quite commonly found in the absence of such damage, however. Those patients with no demonstrable aneurysm had a lower morbidity than the others, a finding which was clearly associated with a lower incidence of brain damage.

Depressive states did not show a more definite relationship to physical disability or to intellectual and personality impairment than they did to brain damage generally—that is, depression did not seem to be mainly a reaction to disability, although in many cases such an element was present. This aspect will be considered in more detail in a later publication.

The findings of 13 patients with improved personalities was unexpected, and seems to represent an effect of leucotomy. This is supported by the fact that most of the patients had A.C. aneurysms, which tend to damage the frontal lobes particularly. Vascular spasm, associated with subarachnoid haemorrhage from aneurysms at any site, may lead to patchy infarction anywhere in the brain, so that five cases that did not have A.C. aneurysms could still have had some frontal-lobe infarction.

The purely psychological reaction to a serious illness may lead a patient to reconsider his ways, change his attitudes to other people, etc., and this may have played a part. However, the nature of the changes and association with A.C. aneurysms make it more likely that this is indeed a leucotomy effect. Similar findings have been made by Logue *et al.* (1967, to be published).

The most important practical finding is that patients with M.C. aneurysms did worse with operative treatment than when treated conservatively. This was most noticeable in women, but it also occurred in men. Men, however, have a better chance of survival with surgery, and it is probable that their increased morbidity is because some of those more severely damaged, who might otherwise have died, have been saved by surgery ; and the findings here do not affect the policy of operating in these patients. In women, on the other hand, there is no increased survival rate with surgery, and it is probable that the cause lies in the morphological and neuropathological differences in M.C. aneurysms in women (Crompton, 1962). These aneurysms are more difficult to treat, and the added brain damage due to surgical exposure of the aneurysm is presumably responsible for the worse results after operation.

However, since the period during which many of the cases in this study were treated there has been a change in the preferred timing of operation, with a consequent improvement in mortality figures. These results have not yet been fully assessed or published, but it is our intention to follow up an adequate sample of women with M.C. aneurysms treated by operation on the fourth to sixth days, to see whether or not there has been a consequent lessening of psychiatric morbidity.

It is understandable that left-sided aneurysms should do worse with surgery, as is the case with women here, when the dominant hemisphere is involved. It is not clear why in men right-sided aneurysms should lead to a higher morbidity. Inspection of the original findings does not suggest a markedly different pattern of disability, although there is an overall tendency in M.C. aneurysms for right-sided lesions to be associated with a greater incidence of psychiatric symptoms and left-sided aneurysms with more intellectual impairment, and for there to be an equal incidence of personality impairment with right- and left-sided lesions.

The incidence of epilepsy, 10%, along with its distribution, is very similar to that found by Rose and Sarner (1965), who studied a larger material from the same neurosurgical department. There is a full discussion of the subject in their paper.

Employment status has not been considered separately as a measure of recovery, although always taken into account. Men in some occupations, mainly in large organizations, seemed often to be accepted by the management and carried by their workmates even when clearly incapable of full work. This was found in the case of a senior managerial executive who continued to draw full salary although suffering from marked intellectual and personality impairment ; but it was much commoner in lower employment levels. Self-employed people doing skilled or professional work seemed to suffer more from any given level of disability. Other patients were found who had retired or had changed their work, on medical grounds, unnecessarily—often because of exaggerated fears of exertion. The whole matter is closely linked with economic conditions and attitudes towards the handicapped, so that one would expect differences between various countries and various periods.

Appendix 1

Overall Mental Disability.—This is a five-point rating scale. Most weight is placed on permanent changes; transient anxiety and depression, even if severe, are considered to be less important than intellectual and personality damage.

Absent or Minimal Disability.—Includes those with only minor memory impairment (forgetfulness), and those with transient anxiety/depressive states not seeking or requiring treatment.

Mild Disability.—Comprises those with intellectual impairment which allows adequate functioning in nonintellectual occupations, those in whom personality change is not sufficient to lead to deterioration in family or other relationships, and those with depression or anxiety states responding to treatment —either as inpatients or as outpatients.

Moderate Disability.—Includes those with definite impairment of work status unless completely unskilled ; deterioration in personal relationships and subjective well-being ; severe and prolonged depression not responding fully to inpatient treatment even in the absence of other changes.

Severe Disability.—In this section are included those with personality and intellectual impairment, or both, severe enough to lead to unemployment or a pronounced fall in employment status ; marked deterioration in family relationships and subjective well-being, or both ; and severe prolonged depression not responding fully to inpatient treatment, in conjunction with otherwise moderate intellectual and personality damage. This category contains patients who are largely incapable of independent life and need institutional care or the protection of a tolerant family.

Very Severe Disability.—Includes those who are grossly demented, inaccessible, bedfast, and often grossly dysphasic. Two such cases were being nursed at home, the others were in institutions.

Appendix 2 : Rating Scales of Impairment and Disability

Each patient was initially rated on a four-point scale of impairment or disability (absent, slight, moderate, severe) on each of the following:

Personality Impairment.—In this rating the opinion of the other informants was regarded as most important. On the whole the changes were those commonly recognized as " organic personality change," with loss of drive and vitality, irritability, easily provoked anxiety, dependence, emotional lability, etc.

Psychiatric Symptoms.—These were almost entirely depressive states and anxiety symptoms, often together. Both lasting and limited illnesses are included, but symptoms restricted to the first three months of convalescence are excluded. In patients whose symptoms had cleared up before the follow-up examination it was sometimes difficult to assess severity, but most of these rated as severe cases had had inpatient or prolonged outpatient treatment ; most rated moderate had had outpatient treatment. However, several of those rated moderate, and who were also brain-damaged, had not had psychiatric treatment. In patients with pre-existing anxiety or depressive states, only a worsening is counted in the ratings. Epileptic syndromes are not included.

Intellectual Impairment.—In this rating the results of the Benton visual retention test and the Inglis paired associates test are ignored. The rating is based on accounts given by the patient and other informants, the results of simple clinical tests (orientation, digit span, remembering a name and address, simple calculations, serial seven subtraction, knowledge of current affairs, etc.), and the general impression made ; at the same time taking into account the patient's background and presumed previous intelligence. The rating of severe is equivalent to frank dementia ; mild rating to some impairment of recent memory and higher intellectual abilities, but compatible with no loss of employment status except in professional, executive, and similar occupations. Moderate impairment falls between the two above, and is usually associated with a drop in employment status.

Physical Disability.—This excludes purely ocular disabilities, and refers mainly to the consequences of weakness or other disturbances of the limbs. Those with C.N.S. signs are not included unless there is frank disability—which depends mainly on the severity of the signs and the nature of the patient's work.

Summary

Some results of a psychiatric study of 261 cases of subarachnoid haemorrhage are presented, dealing especially with comparisons between operative and conservative treatment of 209 patients with single aneurysms of the posterior communicating (P.C.), middle cerebral (M.C.), and anterior communicating (A.C.) arteries. The background and trial organization are briefly described.

Psychiatric morbidity is high. Of those with aneurysms in the trial comparisons 45% were regarded as unimpaired or nearly so ; 24% were mildly, 18% moderately, 10% severely, and 3% very severely affected. Patients with no demonstrable aneurysms (30) had lower morbidity rates.

Most of the psychiatric and psychological morbidity is due to brain damage, but anxiety and depressive states also occur in the absence of such damage, and may be very severe.

Patients with M.C. aneurysms have a significantly higher morbidity with surgical than with conservative treatment, especially women with left-sided lesions. Possible reasons for this are mentioned. Patients with aneurysms at other sites do slightly but not significantly better with surgery.

A group of 13 patients with apparently improved personalities is described. This improvement is regarded as a leucotomy effect.

The incidence of epilepsy is 10% overall in patients with single aneurysms. No case of epilepsy occurred in those with A.C. aneurysms or with no demonstrable aneurysm. The rate was 24% in those with M.C. and 7% in those with P.C. aneurysms. There was no difference between operative and conservative treatment in this respect.

Several tables have had to be omitted to save space. Details will be sent on request.

I wish to express my gratitude to all those who made this study possible. The patients examined were under the care of Mr. Wylie McKissock, who originally suggested the study, Mr. A. E. Richardson, and Mr. L. S. Walsh, all of whom gave every help and much valuable advice. Professor Desmond Curran provided me with facilities and gave me encouragement. I have had essential statistical advice from Mr. P. M. Payne and Mr. H. Gwynne Jones ; and there are many others, not named here, to whom I am also most grateful. Financial support for computer analysis was provided by St. George's Hospital Medical School.

Psychiatric Aspects of Pernicious Anaemia: A Prospective Controlled Investigation

RALPH SHULMAN,* M.B., CH.B., M.R.C.P.ED., M.R.C.P.GLASG., D.P.M.

Brit. med. J., 1967, **3**, 266–270

Though a wide spectrum of psychiatric symptoms has been attributed to vitamin-B_{12} deficiency, the factors which predispose individuals to this form of illness rather than to haematological or neurological manifestations remain unknown. The frequency of mental symptoms in pernicious anaemia has not been established. Inquiries based on the retrospective analysis of general hospital case records have reported mental symptoms in only 2 to 4% of patients (Young, 1932 ; Cox, 1962), whereas in selected patients with chronic neurological disabilities the incidence of such symptoms has been as high as 60% (McAlpine, 1929 ; Holmes, 1956). No investigations to date have been carried out prospectively on unselected patients with pernicious anaemia admitted to general hospitals, and none have controlled the non-specific effects of physical illness and fatigue on the mental states of patients. Despite these uncertainties, interest in the psychiatric symptoms of pernicious anaemia has been renewed and routine screening tests to detect latent pernicious anaemia have been advocated for all psychiatric patients (Strachan and Henderson, 1965 ; Hunter and Matthews, 1965).

The present investigations were carried out, firstly, to determine the incidence of psychiatric symptoms in patients with pernicious anaemia and, secondly, to evaluate the importance of vitamin-B_{12} deficiency in their development. The method used was a comparison of the psychiatric symptoms in patients with pernicious anaemia and in a control series of patients with other types of anaemia, both groups being matched for age, sex, and haemoglobin level. It was predicted that if vitamin-B_{12} deficiency caused mental symptoms, their incidence would be higher in the pernicious anaemia group and their remission would not occur until after treatment with vitamin B_{12}.

Selection of Patients

Pernicious Anaemia.—Patients with suspected pernicious anaemia were seen through the co-operation of physicians and

Requests for reprints should be sent to Dr. R. Shulman, Riverview Hospital, Essondale, Vancouver, British Columbia, Canada.

haematologists, and treatment with vitamin B_{12} was withheld until the first psychiatric interview had been completed. In many of the patients a definitive haematological diagnosis had not been established, and several patients were later transferred to the control series when complete investigations had shown a normoblastic type of anaemia. In this way some of the interviews were carried out blindly. Between 1963 and 1966 38 patients were referred as possible cases of pernicious anaemia and interviewed before treatment had begun. Of the 38 patients, 27 are described in this report—25 with Addisonian pernicious anaemia and two with post-gastrectomy intrinsic factor deficiency. Of the remaining patients, two were excluded because of uncertainty in the final diagnosis. Six were transferred to the control series, and three were rejected because of difficulties in examining the mental state on account of deafness, mental subnormality, and advanced physical deterioration.

Control Patients.—The criterion for admission to the control group was a presentation with symptoms of anaemia with little evidence of disabling primary disease. To avoid possible bias in the frequency of psychiatric symptoms in the control group, patients with the following types of anaemia were excluded: (1) anaemia associated with chronic infective and toxic conditions such as renal disease, ulcerative colitis, etc.; (2) anaemia of carcinomatosis and reticuloses; (3) acute haemorrhagic anaemia; (4) pregnancy anaemia; and (5) folate deficiency megaloblastic anaemia. Twenty-one control patients were examined, 18 with chronic iron-deficiency anaemia, two with primary hypoplastic anaemia, and one with a benign haemolytic anaemia.

Methods of Examination

The examination consisted of an interview, a psychological test for organic brain damage, and a personality questionary.

Interview.—Two or more interviews were carried out, the first before treatment, and the second early in treatment at the time of the maximum reticulocyte response. The length and structure of the interviews varied with the physical state of the patients. At every interview the mental state was formally examined for changes in affect, orientation, and intellectual function and for the presence of obsessional symptoms, hallucinations, and delusions. Most patients were well enough to allow a comprehensive history to be taken and when possible the interview was conducted in a private room.

Psychological Test.—The synonym learning test (S.L.T.), an auditory word-learning test, was administered to patients before and after treatment with vitamin B_{12}. This test contains a factor of short-term memory and has been validated and standardized on an elderly psychiatric population (Kendrick *et al.*, 1965; Kendrick, 1965). Patients of low intelligence may be misclassified as brain damaged on this test (Kendrick, 1964), and for this reason all the patients had their verbal intelligence assessed on the synonym section of the Mill Hill vocabulary scale Form I Senior (Raven, 1958).

Questionary.—After their mental state had returned to normal, patients were given the Maudsley personality inventory to complete. This questionary measures two dimensions, neuroticism (N) and extroversion (E) by means of a self-rating scale of 48 questions (Eysenck, 1959).

Assessment of Psychiatric Symptoms and Method of Rating

Some of the symptoms which occur in the psychoneuroses and in depression may also be found in patients with anaemia who have no psychiatric illness. In the present investigations, for example, fatigue and loss of weight were regarded as physical and not psychogenic in origin. The severity of the psychiatric symptoms was measured by the degree to which *psychiatric* symptoms had interfered with the normal habitual activities of the patient. In terms of social disability three grades were defined: (1) mild, if disability occurred in one or more minor areas only—for example, recreation; (2) moderate, if working-time or efficiency had been appreciably diminished; and (3) severe, if unable to follow usual employment.

With this method of rating symptoms it was sometimes necessary to judge whether disability had been caused by psychiatric symptoms rather than by physical incapacity. In general it was possible to make this distinction, and when there was doubt the disability was not regarded as psychiatric.

Follow-up Study

Patients were asked to co-operate in a follow-up study after leaving hospital by a home visit, an outpatient appointment, or a postal questionary.

Results

Incidence and Severity of Psychiatric Symptoms

The psychiatric symptoms included depression, anxiety, loss of libido, irritability, poor concentration, and impaired memory. The only paranoid state encountered was in one of the control patients. Some psychiatric symptoms were present in 82% of the pernicious anaemia patients compared with 52% of the controls, the higher incidence in the former group reflecting symptoms rated as mild. Psychiatric symptoms rated as moderate or severe were present in approximately one-third of both groups of patients. Six of the patients with pernicious anaemia and three of the control patients had a moderate or severe depression.

Incidence and Severity of Psychiatric Symptoms

	Pernicious Anaemia Patients				Control Anaemic Patients			
	Mild	Mod.	Severe	Total	Mild	Mod.	Severe	Total
Normal ..				5				10
Depression..	7	4	2	13	4	2	1	7
Memory impaired ..	4	1	2	7	1	1	1	3
Irritable ..	2			2				
Paranoid state							1	1
Total ..	13	5	4	27	5	3	3	21

Factors Predisposing to Psychiatric Symptoms

Physical.—In pernicious anaemia the presence or severity of the psychiatric symptoms did not correlate with age, duration of illness, physical complications of the illness, loss of weight, neurological involvement, haemoglobin level, or serum vitamin-B_{12} levels.

Psychological.—The neuroticism score on the Maudsley personality inventory did not correlate with the presence of psychiatric symptoms. There was, however, a positive association between depressive symptoms in pernicious anaemia and a past history of depressive illness ($\chi^2=6.51$; $P<0.02$). Of the 13 depressed patients, seven had a personal or family history of depressive illness. Among the 14 patients who were not depressed, none had a history of previous depression.

Effect of Hospital Admission on Mental State of Patients

Early in this investigation it was observed that the psychiatric histories given by the pernicious anaemia patients did not correspond with their mental states shortly after admission to hospital. Eight of the patients reported that their mood had returned to normal shortly after or even before admission to hospital, and related this to the excellent prognosis received from their physicians. This tendency to spontaneous remission was well illustrated in the following case.

The patient, a 47-year-old policeman, had previously been in excellent physical and mental health. To siblings had a history of depression, treated with electric convulsion treatment. For six months the patient had become increasingly concerned by unexplained fatigue. He lost his confidence and became unable to control traffic or meet people. He became deeply depressed with ideas of unworthiness. Suicidal thoughts were present and he was referred for a psychiatric opinion. A blood count showed the presence of a macrocytic anaemia. He was told the result of the test and was referred to a physician. For the next two weeks while he was on the waiting-list for admission to a medical ward his depression remitted completely. "I was better as soon as I knew that it was my blood and not my nerves, doctor." At the first psychiatric interview his mental state was completely normal except for impaired memory on the synonym-learning test.

In most of the control patients the cause of anaemia was unknown on admission and the prognosis was uncertain. Not surprisingly, fewer of the control anaemic patients showed spontaneous improvement after hospital admission.

Memory Impairment: The Synonym-learning Test (Figs. 1 and 2)

Of 24 pernicious anaemia patients, 17 showed abnormal short-term memory on the synonym-learning test, with scores in the range (0–53) associated with brain damage. In pernicious anaemia a brain-damage score was not related either to age or to haemoglobin level. Of the 21 control patients, 16 also had brain-damage scores on this test, but in this group there was a positive correlation between advanced age and an increasingly abnormal score (+0.44; $P<0.01$ Kendall's τ; Siegel, 1956).

FIG. 2.—Relation between age, haemoglobin level, and performance on the synonym-learning test in control anaemic patients.

Effects of Vitamin B_{12}

On the Mental State.—At the second psychiatric interview 10 of the patients declared that they were more cheerful and were taking a new interest in ward activities and conversations. Confirmation of this improvement was sought whenever possible by an interview with the sister and resident doctor in charge of the ward. Nevertheless, it proved difficult to assess whether these changes in mood were the continuation of a previously noted spontaneous remission, the effects of the vitamin-B_{12} injections, or a combination of both. Fourteen patients reported an increased well-being and mental alertness which they had not experienced until after the vitamin-B_{12} treatment. None of the control patients, except two who had received large blood transfusions, were able to record a comparable feeling of well-being and alertness in the early phase of treatment.

On the Synonym-learning Test.—Twelve patients with brain-damage scores agreed to be retested, and nine of them were found to have a normal score early in treatment. After the first vitamin-B_{12} injection the time for the synonym-learning test score to return to normal varied between 10 and 27 days, with a mean interval of 16 days. Serial testing in two patients revealed a considerable improvement on their synonym-learning test scores as early as 20 hours after the first injection. Three patients with persistently abnormal scores had clinical evidence of senile and arteriosclerotic dementia; and during the follow-up study two of them were found to have died after a stroke.

Follow-up Study

The results of a follow-up study one year after leaving hospital are incomplete, since only nine of the pernicious anaemia patients returned a postal questionary or attended for interview. Of this small number, three have relapsed with depressive symptoms despite regular vitamin-B_{12} injections and the maintenance of normal blood values. One other patient has required admission to a psychiatric unit for management of his depression with electric convulsion treatment.

Discussion

In pernicious anaemia the accompanying psychiatric symptoms do not necessarily have a uniform relation to vitamin-B_{12} deficiency. The present investigation has suggested that the main syndromes encountered—depression and memory impairment—have a different origin and significance.

Depression in Pernicious Anaemia

Klerman (1966), in a review of antidepressant drugs, has commented on the frequency of depressive symptoms in conjunction with acute and chronic physical illness. Psychiatric studies in general medical wards have reported that 20% of the patients developed a clinical depression after the onset of an illness likely to be fatal or severely disabling (Helsborg, 1958 ; Stewart *et al.*, 1965). If minor neurotic symptoms had been included the frequency of depressive reactions would have been higher. The results of the present investigations in which 6 out of 27 pernicious anaemia patients and 3 out of 21 control patients developed a moderate or severe depression are consistent with these previous studies.

Patients attributed their depression to the consequences of their physical handicap. It is of interest that after they had received a favourable prognosis many of the pernicious anaemia patients showed a spontaneous remission of depressive symptoms before treatment with vitamin B_{12}. Had this investigation been carried out retrospectively these remissions might have been attributed to the effect of specific therapy with vitamin B_{12}. Because there were patients in both groups who did not develop psychiatric symptoms or in whom such symptoms were mild despite severe physical incapacity, personality characteristics and constitutional factors may have been decisive in determining the appearance of psychiatric sequelae. Evidence that those who developed depressive symptoms were constitutionally vulnerable was indicated by their high incidence of previous depressive reactions, and by a tendency to relapse after discharge from hospital.

In summary, the evidence relating to vitamin-B_{12} deficiency and depressive illness is tenuous. Depressive symptoms are not more common in pernicious anaemia than in other types of disabling physical illness. When depression accompanies pernicious anaemia it would appear to be related less to the direct effect of vitamin-B_{12} deficiency than to the uncovering of a constitutional predisposition to depressive illness precipitated by the anxiety of unexplained fatigue and physical incapacity.

Loss of Memory and Pernicious Anaemia

In pernicious anaemia a short-term loss of memory has been demonstrated on the synonym-learning test. In contrast with the control series this memory impairment was independent of age or anaemia. Memory changes may occur in depression, but few of the patients were clinically depressed at the time of testing. After receiving vitamin B_{12} many patients experienced a rapid sense of well-being and mental alertness. The cellular effects of vitamin B_{12} can be observed after a few hours without implicating placebo-responders. Cells in the bone marrow begin to revert to normoblastic type after nine hours, and in bone-marrow cultures the R.N.A./D.N.A. ratio in the cell returns completely to normal within 24 to 48 hours (Thomas and Lochte, 1958). After one week electroencephalographic abnormalities begin to improve (Samson *et al.*, 1952 ; Walton *et al.*, 1954) and cerebral oxygen consumption shows a moderate increase (Scheinberg, 1951). The earliest changes in the synonym-learning test were observed after 20 hours ; in nine patients a reversion to completely normal scores on this test took on average 16 days. Parallel electroencephalograms would have been interesting, but facilities for this were not available.

Did the nine patients with reversible synonym-learning test scores after vitamin B_{12} have a mild dysmnesic syndrome, and if untreated could this have proceeded to an established dementia ? Recent evidence suggests a hypothetical, biochemical, and pathological basis for memory disturbances in pernicious anaemia. Vitamin B_{12} has been implicated in the enzymatic incorporation of amino-acids into proteins (Neill and Weaver, 1958) and in the synthesis of R.N.A. (Nieweg *et al.*, 1952). Memory may be encoded and preserved in the molecular structure of certain nucleic acids, including R.N.A. (Dingman and Sporn, 1961). Intact hippocampal and mammillary zones are essential for the process of remembering (Brierley, 1961), and damage to those areas has been described in pernicious anaemia (Ferraro *et al.*, 1945).

Misdiagnosis of Psychiatric Illness in Pernicious Anaemia

In both the anaemic and vitamin-B_{12}-deficient patients physical fatigue was the most common symptom encountered, and was frequently the initial symptom. In several patients this unexplained fatigue had resulted in psychiatric referral as cases of neurosis or neurasthenia. One patient with an earlier history of difficulty in swallowing associated with a Plummer–Vinson syndrome had been referred as a case of hysteria.

Vitamin-B_{12} Deficiency as a Cause of Psychiatric Illness

Studies of serum vitamin-B_{12} levels in mental hospital patients have indicated some of the difficulties which exist in attributing the psychiatric illness to vitamin-B_{12} deficiency (Edwin *et al.*, 1965 ; Hansen *et al.*, 1966 ; Shulman, 1967a, 1967b). In a survey of 1,012 psychiatric patients 0.88% were found to have pernicious anaemia (Henderson *et al.*, 1966). This is no higher than the incidence of pernicious anaemia in a normal population. Latent pernicious anaemia is present in 5 to 6% of patients with iron-deficiency anaemia (Beveridge *et al.*, 1965 ; Dagg *et al.*, 1966). From epidemiological data on the incidence of iron-deficiency anaemia (Kilpatrick, 1961) the normal incidence of pernicious anaemia is 0.5%, rising to 1% over the age of 65. The results of the present investigation have suggested that except in the organic psychoses there is little evidence to support the mass screening of psychiatric patients for vitamin-B_{12} deficiency. Even when dementia occurs in pernicious anaemia it is often impossible to exclude a coincidental arteriosclerotic or senile dementia, as in three of the patients in the present report.

It is concluded that psychiatrists should be alert to the possibility of vitamin-B_{12} deficiency in three situations: patients thought to be at risk clinically—for example, anaemic or post-gastrectomy patients, patients with unexplained fatigue, and patients with confusional states or dementia of unknown origin.

Summary

The psychiatric status of 27 patients with pernicious anaemia and 21 control anaemic patients is described. Approximately one-third of both groups had psychiatric symptoms rated as moderate or severe.

Before treatment the most frequent symptoms were depression and memory impairment. Of the psychiatric symptoms encountered only memory impairment appeared to be related to vitamin-B_{12} deficiency. The role of vitamin-B_{12} deficiency in the production of mental symptoms is reviewed. Except for research purposes there is no evidence to support the routine screening of psychiatric patients for pernicious anaemia.

I am grateful to the many physicians and haematologists who co-operated in this investigation, and would especially like to thank Dr. L. Bernstock, consultant clinical pathologist, St. Helier Hospital, for continued interest and encouragement ; Dr. C. K. Kendrick for instruction in the use of the synonym-learning test ; and Mr. W. I. Hume for assistance with the statistical analysis.

Part of this investigation was submitted as a dissertation for the Academic Postgraduate Diploma in Psychological Medicine, University of London, 1964.

Stenosis and Occlusion of Vessels in Cerebral Infarction

S. K. BATTACHARJI,* M.B., CH.B., PH.D.; E. C. HUTCHINSON,* M.D., F.R.C.P.;
A. J. McCALL,* M.D., F.R.C.P., F.C.PATH.

Brit. med. J., 1967, 3, 270–274

The contribution of cerebral vascular disease to the morbidity and mortality of an ageing population has led to a notable increase in studies of the condition in many branches of medicine. Stenosis and occlusion of the extracranial part of the cerebral blood supply has been the subject of several pathological studies (Hutchinson and Yates, 1957; Duffy and Jacobs, 1958; Martin *et al.*, 1960; McGee *et al.*, 1962). Schwartz and Mitchell (1961) reported on the results of a study of the neck vessels in 93 unselected necropsies. They showed that atheroma of the neck vessels increased with age in all patients and that stenosis of severe degree may occur without evidence of cerebral infarction. On their findings they accepted a direct relation between thrombotic occlusion of neck vessels and cerebral infarction but felt that the significance of stenosis in this context was uncertain.

This communication concerns part of a study of the pathology of cerebral infarction and reports the prevalence of stenosis and occlusion of the cerebral arteries in a series of patients with cerebral infarction and compares these findings with an unselected series of patients who died of unrelated causes.

Material and Methods

The material for the study was obtained from 145 necropsies performed at the North Staffordshire Royal Infirmary. During the time of the investigation all 57 cases found to have a cerebral infarct were included in the infarct group. Cases of emboli obviously arising from the heart and cases of paradoxical embolism were excluded. The control group consisted of 88 cases where there was no evidence of cerebral infarction and the age at death was over 45. No deliberate selection was made, but as it was not always possible to remove the cervical spine in a particular case coming to necropsy the cases were not consecutive.

The brain was removed and fixed in 10% formalin in the routine manner. The arch of the aorta was divided above the aortic valve at the level of the third dorsal vertebra; the subclavian arteries were divided beyond the origin of the vertebral arteries and the major vessels were then mobilized. After sectioning the cervical spine at the level of the seventh cervical vertebra a saw cut was made through the base of the skull on a line which ran through the anterior, middle, and posterior fossae on both sides. This provided a specimen containing the aorta and the neck vessels throughout their entire course. The carotid arteries were then exposed in the carotid canal with bone forceps. After examination of the arch of the aorta, the innominate artery, the common and internal carotid arteries, the subclavian artery, and the extravertebral part of the vertebral artery were examined by transverse section at 1-cm. intervals throughout their course. The cervical spine was decalcified with 10% hydrochloric acid and after three weeks the vertebral portion of the vertebral artery was exposed and examined.

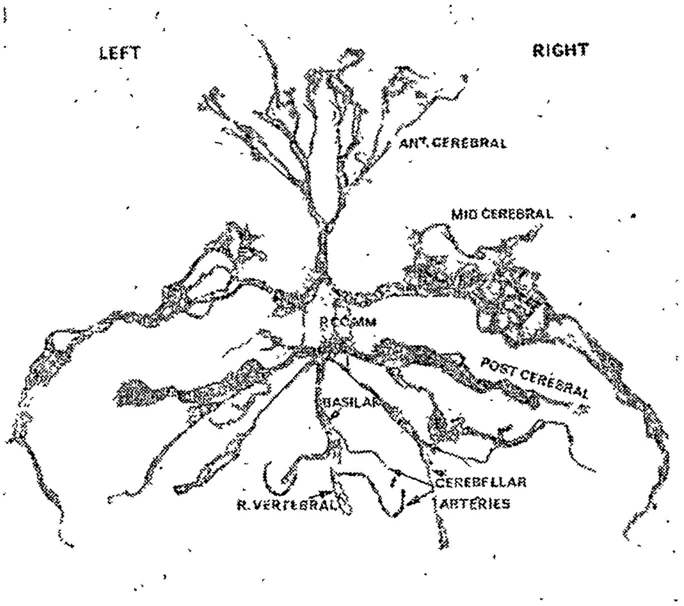

FIG. 1.—Specimen showing the intracranial vessels dissected from the brain preparatory to examination for stenosis and occlusion.

---

* North Staffordshire Royal Infirmary, Stoke-on-Trent.

Dr. Battacharji was awarded the Ph.D. at the University of Birmingham for a thesis entitled "The Role of Extracranial and Intracranial Arteries in Cerebral Infarction"

After fixation of the brain the remainder of the cerebral arteries were dissected free with blunt forceps. The circle of Willis, the basilar artery, and the arteries to the cerebellum and brain stem were first freed; the dissection was then continued and the major branches of the circle of Willis—the anterior, middle, and posterior cerebral arteries—were removed from the hemispheres (Fig. 1). The whole specimen was then floated in water for examination, and the extent of atheroma and degree of stenosis of vessels from their origin to their termination in the gyri were noted. The brain was examined by serial coronal sections 1 cm. thick and the extent of macroscopic infarction charted on a diagram.

In each specimen the vascular changes were classified in the following manner. The distribution of the arterial lesion was first noted on an outline diagram of the vascular supply. The nature of the vascular change was then recorded—that is, fatty streaks, fibrous plaques, plaques with softening, intramural haemorrhage, calcification—ulceration of the surface of the lesion and thrombus were noted separately. The degree of stenosis was classified as follows: grade 0, no encroachment on the lumen; grade 1, less than 25% reduction of lumen; grade 2, 25 to 50% reduction of lumen; grade 3, more than 50% reduction of lumen but no occlusion; grade 4, total occlusion.

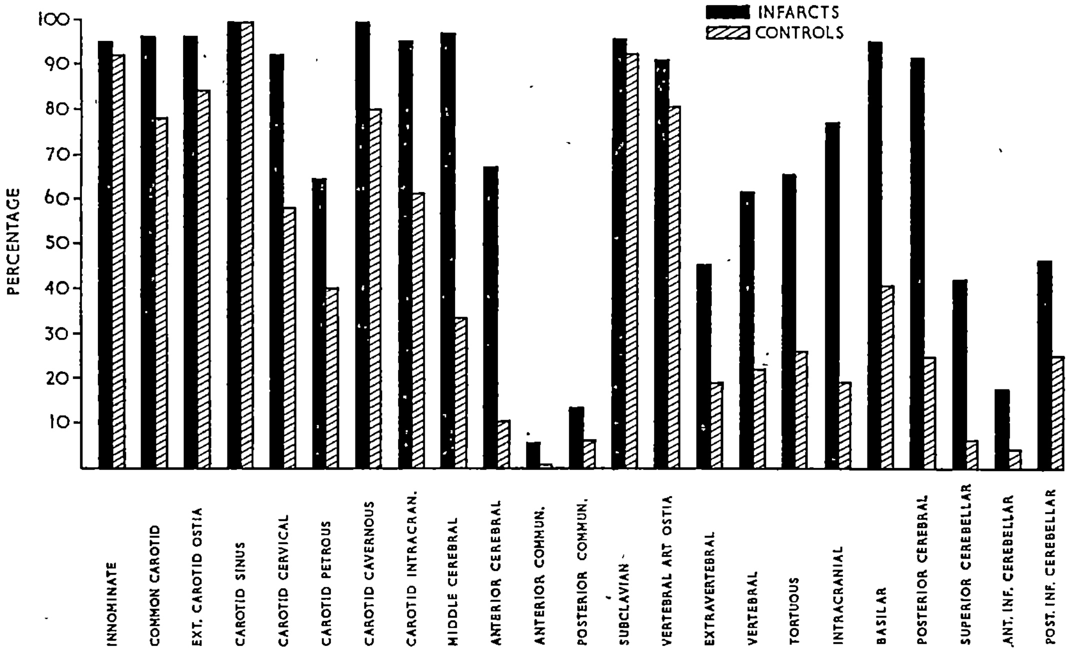

FIG. 2.—Distribution of all macroscopic vascular changes of the extracranial and intracranial vessels of the right side.

For each specimen the vascular change was recorded at multiple sites. In the carotid circulation the innominate artery, the common carotid, the external carotid ostia, the carotid sinus, and the cervical, cavernous, petrous, and intracranial portions of the carotid proximal to its primary division within the skull were assessed separately. In the vertebral circulation the subclavian, the vertebral artery ostia, the extravertebral portion of the artery, and the vertebral, tortuous, and intracranial parts of the vertebral artery were noted individually. The other intracranial arteries were scored according to the maximum degree of stenosis noted along the course of the individual vessel. For convenience, throughout the text the term "extracranial vessels" includes the terminal parts of the carotid and vertebral arteries within the skull. The term "intracranial vessels" refers to the branches of the carotid and vertebral arteries lying below the brain and within its substance.

All the dissections were done by one of us (S. K. B.); the vascular changes were assessed independently by the others (E. C. H. and A. J. M.), who were unaware of the state of the brain at the time of this assessment.

Results

Age and Sex Distribution

The age distribution in the infarct and control groups is shown in Table I. At death only 3 of the 57 with infarcts were below 60, whereas 22 of the 88 controls were between 40 and 60. In contrast, 15 with infarcts and only six controls were over 80 at death. The average age of the infarct group at death was 72.4 years, compared with 62 years in the control group. However, 68% of the patients in both the infarct and the control group were between 60 and 80 years of age at death.

TABLE I.—*Distribution by Age at Death and Sex of 57 Patients with Infarcts and of 88 Controls*

Cerebral Infarction

Because brain infarcts were frequently multiple, 130 separate areas of infarction were noted in the 57 specimens (Table II). In 12 cases (21%) the infarcts were cortical, in 29 (51%) they were subcortical, and in 16 (28%) both the cortical and the subcortical areas were affected. Table II shows the distribution of infarcts, and it will be seen that there were 107 in the

Basilar	10		11	
Total	107		130	

carotid and 23 in the vertebro-basilar territories. The middle cerebral territories were most often affected, and accounted for all but four of the areas of multiple infarction.

Lesions in Cerebral Blood Supply

This communication is primarily concerned with the prevalence of stenosis or occlusion of the cerebral arteries, but for the sake of completeness we have included in one illustration (Fig. 2) all the macroscopic vascular lesions that were noted in the infarct and control groups. The figures are expressed as a percentage of the total in each group; the findings on the right and left sides are similar and, for the sake of brevity, the changes on the right side only are shown.

In the carotid circulation in the infarct and control groups the carotid sinus showed some change in all specimens. In the infarct group the innominate, the common carotid, and the cervical and cavernous portions of the carotid artery were also affected in over 90% of cases, and in the intracranial branches of the carotid artery the middle cerebral artery was affected to the same degree. In the control series there was a high incidence of vascular lesions at certain sites—for example, the innominate, the common carotid, the cavernous part of the carotid—but compared with the infarct group the changes in the cervical and petrous part of the carotid and in the anterior and middle cerebral vessels were considerably less.

The subclavian and vertebral artery ostia showed changes in over 80% of cases in both the infarct and control groups. In the infarct group the extravertebral portion of the vertebral artery was affected in 44%, compared with 21% of the controls. There was also a higher incidence of lesions within the vertebral canal and in the tortuous and intracranial portions of the vertebral artery in the infarct compared with the control group. In the intracranial branches the incidence of vascular change in the posterior cerebral artery was 91% in the infarct group compared with 25% in the control group.

The lowest incidence of vascular change in both the infarct and the control groups was found in the anterior and posterior communicating arteries and in the anterior inferior cerebellar artery.

Stenosis and Occlusion of Vessels

The incidence and distribution of stenosis (grades 1 to 3) and occlusion of vessels (grade 4) in the two groups are shown in Table III. For simplicity of presentation the numbers observed in each grade are expressed as a percentage of the total in the infarct and control groups. Statistical assessment was made on the numbers in each grade in both groups. It was often necessary to combine grades 3 and 4 and sometimes grades 2, 3, and 4 in order to provide groups of sufficient size. The χ^2 test was applied when three or more groups were combined, but for two groups the tables of Mainland *et al.* (1956) were used. The level of $P<0.05$ was accepted as significant.

When the extracranial vessels of the two groups were compared the innominate and subclavian arteries were the only vessels in the infarct group which failed to reach this level of significance when compared with the control group. Of the intracranial vessels the anterior inferior cerebellar and the communicating arteries were the only vessels in the infarct group which failed to show a significantly higher incidence of stenosis when compared with the controls.

If a severe degree of stenosis (grade 3) is considered in isolation certain points of interest arise. In the left carotid sinus the incidence of grade 3 stenosis is the same in the control and the infarct group (5%), and in the left cavernous sinus the incidence is slightly higher in the controls (3%) than in the infarcts (2%). Elsewhere the incidence of grade 3 stenosis is always higher in the extracranial vessels of the infarct group. The differences are more pronounced in certain intracranial vessels. The middle cerebral artery, for example, showed grade 3 stenosis in 33% of cases on the right side compared with an incidence of 5% in the controls. Less marked but still significant differences were found in the anterior and posterior cerebral arteries and in the posterior inferior cerebellar arteries. In spite of the higher incidence of stenosis in the infarct group it is worth emphasizing that grade 2 stenosis was frequently observed in the control group.

Occlusion of Vessels

One striking difference in vascular lesions between the two groups was that occlusion of vessels was confined to the infarct group. Occlusion of the carotid arteries was found on 64 occasions and occlusion of the vertebral arteries on 30. Of the 64 carotid occlusions, 42 were on the right and 22 on the left side; of the 30 vertebral occlusions, 16 were on the right and 14 on the left. In the intracerebral vessels occlusion was
